$$\text{Suppressed: } q = 3.33 L [(H + h_s)^{\frac{3}{2}} - h_s^{\frac{3}{2}}] \dots \dots \dots (14)$$

Without velocity of approach (i. e., $h_s = 0$)—

$$\text{Contracted } \left\{ \begin{array}{l} \text{Both ends: } q = 3.33 (L - 0.2H) H^{\frac{3}{2}} \dots \dots \dots (15) \\ \text{One end: } q = 3.33 (L - 0.1H) H^{\frac{3}{2}} \dots \dots \dots (16) \end{array} \right.$$

$$\text{Suppressed: } q = 3.33 H^{\frac{3}{2}} \dots \dots \dots (17)$$

The above formulas are very extensively used in the United States. They were deduced by Mr. J. B. Francis, in 1854, from very elaborate experiments which he conducted at Lowell, Mass., on large weirs about 10 feet long. The heads ranged usually from 0.4 to 1.6 feet. The formulas are simple, logical and fairly reliable within the range of the experiments. The heads H were measured 6 ft back from the crest (Fig. 22).

(b) BAZIN'S WEIR FORMULA.

General formula applicable to sharp-crested, suppressed, surface weirs is

$$*q = \left(0.405 + \frac{0.00984}{H} \right) \left[1 + 0.55 \left(\frac{H}{H+p} \right)^2 \right] L H \sqrt{2gH} \dots \dots (18)$$

in which p = height of crest above the bottom (Fig. 22) and the other notation as per Francis' formulas, preceding. This formula (18) takes into consideration the velocity of approach in the height of crest p , hence the former does not require any special treatment when p is known. It should be remarked that the formula was deduced from very careful experiments with standard weirs from 0.656 ft. (0.2 meter) to 6.56 ft. (2 meters) in length and with heads ranging from 2.50 to 1.00 ft., the lower heads for the longer weirs. Care should be used in extending the use of the formula beyond the above range for length L and head H . It should be noted that Bazin measured the head H at points distant $D = 16.4$ ft. back from the crest. (See Fig. 22.)

The above general formula (18) can be simplified for practical use by letting

$$m = \left(0.405 + \frac{0.00984}{H} \right) \left[1 + 0.55 \left(\frac{H}{H+p} \right)^2 \right],$$

$$\text{hence } q = m L H \sqrt{2gH} = m \sqrt{2g} L H \sqrt{H} \dots \dots \dots (19)$$

Either of these two forms (19) may be used in connection with the following table which gives the values of m (and of $m\sqrt{2g}$) for given values of p and H .

The second form, $q = (m\sqrt{2g}) L H \sqrt{H}$ will probably be found more convenient as the table gives average values of $(m\sqrt{2g})$ for each five successive values of H , and intermediate values may be interpolated. If extreme accuracy is required the first form is preferred, remembering that $\sqrt{2gH} = 8.02\sqrt{H}$. Note that the last column in Table 10 gives the limiting value of m for $p = \infty$, whence $m = \left(0.405 + \frac{0.00984}{H} \right)$, the first part of the coefficient, as the latter part reduces to unity. Hence this value of m may be used when there is no velocity of approach, that is, when p is very large.

* The standard weir provides for free admission of air under the falling sheet of water.

10.—VALUES OF THE COEFFICIENT m IN THE FORMULA $q = m L H \sqrt{2gH}$,
FOR A SHARP-CRESTED WEIR WITHOUT LATERAL CONTRACTION,
THE AIR BEING ADMITTED FREELY BENEATH
THE OVERFLOWING SHEET OF NAPPE.

Observed Head = H in Feet.	Values of the coefficient m corresponding to the height p of the weir above the bottom of the channel.										Limiting Value of m for $p = \infty$.

Problem.—What is the discharge through a weir whose crest is 7 ft. long and 2.5 ft. above the bottom; the measured head, H , being 0.75 ft.?

Solution.—The value of m in the preceding table for $p=2.5$ and $H=0.75$, is 0.433; then from first equation (19), $q=0.433 \times 8.02 \times 7 \times 0.75 \times 0.866=15.8$ cu. ft. per second. *Ans.*

(c) FTELEY AND STEARNS' WEIR FORMULAS.

General formula for sharp-crested, suppressed, surface weirs, as

$$\left. \begin{aligned} q &= 0.4125 L H \sqrt{2gH} + 0.007 L \\ &= 3.31 L H \sqrt{H} + 0.007 L \end{aligned} \right\} \text{No velocity of approach} \dots (20)$$

and, if there is velocity of approach,

$$q = 3.31 L (H + 1.5 h_a) \sqrt{H + 1.5 h_a} + 0.007 L \left\{ \begin{array}{l} \text{Including ve-} \\ \text{locity of} \\ \text{approach.} \end{array} \right\} \dots (21)$$

Use notation for Francis' formula, page 1178. The above formulas were deduced from experiments which they made in Boston, Mass., 1877-9, with weirs 5 to 19 ft. long and under heads ranging from 0.065 up to 1.6 feet. The heads H were measured 6 ft. back from the crest.

(d) *PARMLEY'S WEIR FORMULA.

General formula for sharp-crested, surface weirs, either contracted or suppressed, taking into account velocity of approach, if any:

$$q = C' K [L - 0.1 n H] H^{\frac{3}{2}} \dots \dots \dots (22)$$

in which q = discharge in cu. ft. per second;

L = length of weir, in ft.;

n = number of end contractions, as 0, 1 or 2;

H = "surface level" head on crest, in ft.;

C' = constant for given value of H , from Table 11;

K = constant for given value of $\frac{a}{A}$, from Table 12;

a = $(L - 0.1 n H) H$ = contracted area of discharge;

A = area of water section in channel of approach.

* Discussion by W. C. Parmley, Trans. Am. Soc. C. E., Vol. XLIV, p. 351.

Parmley's formula (22) was not deduced from any particular set of experiments, but is based on the experiments and formulas of Bazin, Francis, and Fteley and Stearns. The result obtained is a formula comprehensive in character and giving *average* values. Bazin's experiments were made very carefully under ideal conditions in a long, smooth canal lined with cement, while those of Francis and Fteley and Stearns were conducted under conditions more nearly approaching those to be found in practice. The roughness of the stream or canal must necessarily produce an appreciable effect on the flow.

Triangular and trapezoidal weirs have been proposed in place of the standard, rectangular section, on account of the very slight variation of the coefficient of discharge for different heads H . But they have not yet come into practical use.

The Submerged Weir, so-called because the water level below the weir rises higher than the crest, is shown in Fig. 24.

Fig. 24.—Submerged Weir.

(a) Fteley and Stearns' formula* for submerged weirs, without end contractions is,

$$q = m L \left(H + \frac{h}{2} \right) (H - h)^{\frac{3}{2}} \dots \dots \dots (23)$$

in which q = discharge in cu. ft. per second;
 H = up-stream head on crest, in feet;
 h = down stream head on crest, in feet;
 L = length of weir, in feet;

m = coefficient for given values of $\frac{h}{H}$, as in the following Table.

13.—VALUES OF COEFFICIENT m FOR GIVEN VALUES OF $\frac{h}{H}$.

(Equation 23.)

$\frac{h}{H}$	m	$\frac{h}{H}$	m	$\frac{h}{H}$	m	$\frac{h}{H}$	m	$\frac{h}{H}$	m

Hydraulic Measurements.—Measurements of flowing water may be made by several methods, depending upon the circumstances and requirements of the particular case:

- (1) By tank measurement;
- (2) By venturi meter;
- (3) By weir measurement;
- (4) By pitot-tube meter;
- (5) By floats;
- (6) By current meters.

These are discussed in the order named.

Tank measurement.—This method is the most exact and can be used where the discharge is small. The discharge from a pressure-pipe line leading to a high service reservoir may be measured by using the latter as a tank and shutting off the outlet while it is being filled. The capacity of the reservoir must be determined accurately, or it may be calibrated to gauge readings above the bottom.

Venturi meter.—This is described fully on page 1173, etc. This meter is particularly adapted to measuring the discharge in pipes, and can be had in sizes up to 6 ft. or more in diameter. Results can be obtained usually within 2 or 3 per cent of the actual discharge. In ordering, it is necessary to state the diameter of the pipe and the average velocity of discharge so that the cones and *venturi* may be proportioned correctly, for accurate results. The velocity through the *venturi* must be accelerated sufficiently to cause a marked decrease in pressure, and this is done by giving the diameter of the *venturi* the proper ratio to that of the main pipe. It should be large for high velocities and small for low velocities. A register should accompany each meter.

Weir measurement.—Weir formulas are discussed on page 1177, etc. In constructing a standard weir it is necessary to have the crest perfectly level and the sides vertical. The inner edges of the opening should be sharp and chisel-edged or square cornered. If square cornered the boards or partition should be thin or they may be beveled on the downstream side, thus, . The crest is often formed of a thin sheet of metal fastened on the inside of the wooden partition. Special care must be taken to insure free access of air under the falling sheet of water below (down stream from) the crest, otherwise a partial vacuum will form there, draw the sheet inward toward the weir, and affect the discharge. In measuring the head H on the crest, it is necessary to take the elevation of the water-surface at a sufficient distance D (Fig. 22) above the weir to reach the still-water level, or practically so. Francis used $D = 6$ ft., while

Fig. 25.

Bazin used $D = 16.4$ ft. Hence the distance D may depend somewhat on the formula to be used (see pages 1177 and 1178). There are three methods in use for determining the head H . One is by setting a reading gage in the stream, using the elevation of crest as the datum plane. The second method consists in suspending a plumbbob on the end of a steel tape supported from some point E , Fig. 22, at a known elevation h above the crest, and measuring the vertical distance d to the water surface. Then the required head $H = h - d$. In order to get the measurement d accurately, the plumbbob may be allowed to swing gently, and raised until it just ceases to cause a ripple on the water surface. The third method is by the Hook Gage, shown in Fig. 25. The point of the hook at the bottom of the rod (the hook may be attached to a leveling rod, reading to thousandths of a ft.) is raised until it pierces the "skin" of the surface, raising a slight pimple. The hook is then lowered until the pimple "just" disappears. The elevation is read by the vernier, which should be set at zero when the end of the hook is at the elevation of the crest of the weir.

Pitot tube meter.—The Pitot tube, in its primitive conception, consists essentially of a bent tube (of glass) inserted in a current of water, Fig. 26, with the open end of the lower arm squarely facing the current. Then, theoretically,

will the water rise in the tube to a height $h = \frac{v^2}{2g}$, in which v = velocity at that particular point in ft. per second;

and h = velocity head in ft. due to v . Hence, by measuring the height h of the column of water in the tube, the velocity $v (= \sqrt{2gh})$ is obtained.

For measuring the velocity of flow under pressure, as in pipes, the Pitot tube, complete, comprises two pipes, crudely shown in Fig. 27. One of these pipes terminates as in Fig. 26, and records the velocity head h_v + the pressure head h_p . The other terminates as a piezometer tube in an orifice at right angle to the direction of flow, and records the pressure head h_p alone. It is clearly evident, then, that the difference in elevation of the water levels in the tubes is the velocity head h_v , and that, theoretically, the velocity $v = \sqrt{2gh_v}$ as above.

Fig. 28 shows one of the forms of Pitot tubes used in the Detroit experiments,* to receive the velocity and pressure heads. For accurate reading, the tops of both of the tubes (Fig. 27) are connected by pipes to a differential gauge consisting of two parallel glass tubes with a sliding scale between. The difference in elevation is reduced to h_v as above, or to any other equivalent expression. Mercurial or oil gauges may be used. (See Trans. Am. Soc. C. E., Vol. XLVII, pp. 72-3).

Floats.—These are classed as surface floats, sub-surface floats and rod floats.

Surface floats (Fig. 29) are the least accurate. Prof. Dwight Porter of the Mass. Inst. Tech. says: "These are of little value when run alone, since they are easily affected by wind, and the relation between surface and mean velocity is uncertain. As a rough approximation, the mean velocity in a vertical may be assumed as from 0.9 to 1.0 times the surface velocity in a vertical, and the mean velocity for the entire cross-section of the stream as about 0.8 times the maximum surface velocity."

Sub-surface floats consist of small cylindrical boxes, say 8 or 9 ins. in diameter, and weighted at the bottom section with a small cube of lead. These are suspended from small surface floats to any depth at which it is required to measure the velocity.

Rod floats are the most exact. They are particularly adapted to measuring the flow in canals or in streams where the depth of water is fairly constant. The length of rod should be equal to nearly the depth of the water, should project slightly above the surface and reach nearly to the bottom. They are used frequently in depths exceeding even 30 feet. The advantage of the rod float is that the mean velocity in the vertical is obtained directly

Fig. 26.

Fig. 27.

* See Trans. Am. Soc. C. E., Vol. XLVII, p. 12. Digitized by Google

for any vertical section of the stream or canal in which it is allowed to float at a "timed" rate between two cross-sections of the stream at a given distance apart. The floats may be made of long, tin cylinders about 2 to 2½ ins. in diameter, loaded at the bottom with lead, accurately weighted or adjusted with pebbles, and closed at the top with cork. In measuring the discharge in a canal, the cross-section of the latter is divided into vertical strips of given area, the mean velocity for each of these strips is determined by the rod float, which velocity multiplied by its area gives the discharge for that strip. The total discharge divided by the total area of cross-section gives the mean velocity. The rods are floated through the middle of the strips at the dotted lines shown in Fig. 30, which represents a section of the canal.

Current meters.—Current meters may be expected to give results with error ranging from 3 to 10 per cent. The greatest accuracy will be obtained in canals with a moderately high velocity of flow; the least accuracy in turbulent streams with cross currents, also when the velocity of the water is very slight, or when it contains suspended matter, as in sewers.

There are two principal types of current meters, namely, the cup-wheel meter and the propeller-wheel meter. Fig. 31 illustrates the former type and Fig. 32 the latter. The turns of the wheel which indicate the velocity of the water are registered by an electric meter similar to that shown in Fig. 33. All meters should be tested or rated before being used, as they are sometimes subject to fluctuations which may seriously affect the result. The meter is rated by moving it through still water at given speeds, plotting the results on cross-section paper, with "revolutions per minute" as abscissa, and "velocity in feet per second" as ordinates. The curve drawn through the plotted points is the "rating line" for the meter for immediate use.

Fig. 29.

Fig. 30.

Fig. 31.—Price Meter.

Fig. 32.—Haskell Meter.

The current meter may be used in two ways, namely, by the "method" and by the vertical "integration" method. The former is preferred because more accurate, and consists in holding the meter in a given position or point of the cross-section of the stream, that is, the center of a given area for a definite length of time and noting the register of the meter for that interval. The velocity per second and the discharge for that area are then obtained, and likewise for the other areas. The total discharge of the stream is divided by the total area of cross-section gives the mean velocity. The integration method is quicker but somewhat less accurate unless very

Fig. 83.—Meter Register.

fully done. It consists in lowering the meter from the surface of the water to the bottom and then back again to the surface through the center of each given vertical strip as shown by the dotted lines, Fig. 30. The movement must be slow and constant and the reading of the Register must be for the actual time consumed, beginning and ending with the caps or vanes of the meter well under the surface. The result deduced is the velocity and discharge for that particular vertical strip. The other strips are treated in the same manner, and the resulting mean velocity obtained.

EXCERPTS AND REFERENCES.

Instructions for Installing Weirs, Measuring-Flumes and Water Registers (By C. T. Johnston, and Elwood Mead, Paper, U. S. Dept. of Agriculture, and Bulletin 86, Irrigation Investigations; Eng. News, Aug. 29, 1901).—Illustrations: Fig. 1, arrangement of Cippoletti weir; Fig. 2, measuring flume and register; Figs. 3 and 4, arrangement of pulleys to magnify the record of water registers; Figs. 3a and 4a, arrangement of pulleys to reduce record of water registers; Fig. 5, the Mead stream heights or water register; Fig. 6, the Friez stream heights or water register; Fig. 7, the Leitz stream heights or water register; Fig. 8, the standard stream heights or water register. Descriptions and discussions.

Measurement of the Flow of Water in the Sudbury and Cochituate Aqueducts (By W. W. Patch. Eng. News, June 12, 1902).—Illustration of current meter apparatus; also diagrams.

Current Meter and Weir Discharge Comparisons (By E. C. Murphy. Trans. A. S. C. E., Vol. XLVII).

The Effect of Long Lengths of Hose on Fire Streams (By S. A. Charles. Paper, Am. W. W. Assn., June 12, 1902; Eng. News, July 3, 1902).—Diagram showing heights, volumes and velocities of fire streams for various lengths of hose, size of nozzle and pounds of hydrant or steamer and nozzle pressure—from experiments by S. A. Charles, combined with those of J. R. Freeman. See discussions in Eng. News of July 17 and 31, and Dec. 3, 1902.

The Flow of Water in Wood Pipes (By Theron A. Noble. Trans. A. S. C. E., Vol. XLIX).

Methods of Measuring the Flow of Streams (By J. C. Hoyt. Eng. News, Jan. 14, 1904).—Interesting diagram showing vertical velocity curves for Susquehanna River; also table of velocity determinations. See, also, Eng. News, of Aug. 4, 1904.

Notes on the Computation of Stream Gagings (By O. V. P. Stout. Paper, Sec. of Eng. and Mech., 12th Natl. Irrig. Cong., Nov. 15 to 18, 1904; Eng. News, Dec. 8, 1904).—Formulas and diagrams.

The Hydraulic Plant of the Puget Sound Power Company (By E. H. Warner. Trans. A. S. C. E., Vol. LV).—Table 1, Make-up of steel pipe; Table 3, Experiments on the hydraulics of the timber flume.

Depth of Thread of Mean Velocity in Rivers (By F. W. Hanna. Eng. News, Jan. 11, 1906).—In the measurement of the flow of rivers it is often assumed that the thread of mean velocity lies at approximately 0.6 of the total depth from the surface, varying for extreme cases between the limits of 0.5 and 0.7. There seems to be a general impression that this assumption is not capable of theoretical demonstration. Mr. Hanna proceeds to demonstrate "rationally" that these values are correct, from the assumption that the vertical velocity curve is sensibly a parabola.

An Experiment to Determine "N" in Kutter's Formula (By C. W. Babb. Eng. News, Feb. 1, 1906).—In connection with the work of the Reclamation Service of the St. Mary project in Montana, the values of "n" in earth canal were found to be: .027, .024, .023, .023, .021; average .0236, or practically .025.

Some Experiments on the Frictionless Orifice (By Horace Judd and R. S. King. Paper, Am. Assn. for the Advan. of Science, July, 1906; Eng. News, Sept. 27, 1906).—Diagrams and tables.

Additional Information on the Durability of Wooden Stave Pipe (By A. L. Adams. Trans. A. S. C. E., Vol. LVIII).—Refers to the 7½ miles of wood-stave pipe laid for the Astoria city water works ten years previously. As a result of examination of the pipe line, the following conclusions are drawn: (1) Staves which are constantly subject to water pressure from within and are buried in the ground, may be very short-lived. (2) The magnitude of the water pressure, beyond a moderate head, has but little or no influence in preserving the timber. (3) The pipe laid above ground as not deteriorated to any considerable extent, nor has the pipe laid in the trenches leading from the distributing reservoir. (4) Where buried, its durability has depended upon the soil conditions and the depth of backfill. (5) When the depth of backfill has exceeded 2 ft. above the pipe, and the material has been free from vegetable matter, and has been of a fine

and impervious character, much less deterioration has taken place. (6) Whenever the staves have been in contact with loamy earth or earth containing vegetable matter, or wherever they have been covered with porous material, or to a depth less than 2 ft., rapid decay has resulted. (7) Decayed staves have been found all around the pipe. (8) Sound staves have been frequently found contiguous to badly decayed staves. (9) The character of the grain, whether slash or grain edge, has not influenced the durability. (10) The bruising of the staves during the process of erecting seems to have been one of the chief agencies in hastening decay. (11) Decay has not been confined to the outside of the pipe. (12) The pipe has not usually shown leakage as long as sound wood has remained in excess of $\frac{1}{4}$ " in thickness. (13) The malleable cast band fastenings have been found to be in good condition. (14) The bands, $\frac{1}{4}$ " in size, have been considerably corroded save where secured by the nut, but all have been used again by placing the nut in its original position. (15) "The pipe in the 2nd and 3rd Sections, $2\frac{1}{2}$ miles, is nearly all buried in fine-grained sand, and will last perhaps 10 years more by giving it a general repairing, say 5 years hence, but the greater part of the 1st and 4th Sections will have to be replaced in about 4 years.—Superintendent." For Mr. Adam's original paper, see Trans. A. S. C. E., Vol. XXXVI; see also Trans., Vol. XLI.

The Kinetic Energy of Flowing Water (By L. F. Harza. Eng. News, Mar. 7, 1907).—Formulas for the energy in rivers, streams, pipes, etc.

Observations to Determine Values of "C" and "N" as Used in Kutter's Formula (By J. B. Lippincott).—Eight experiments described: *Exper. No. 1.*—Tunnel 446 ft. long, floor grade 0.00096, rectangular section 4 $\frac{1}{2}$ ' wide x 4' deep with semi-circular arch and finished with a 1:3 cement mortar plaster. *Exper. No. 2.*—Tunnel 318 ft. long, floor grade 0.00095, section and finish same as No. 1. *Exper. No. 3.*—Canal, 800-ft. length, trapezoidal section with slopes 1:1 and bottom width 11.5 ft., concrete lined with 1:3 mortar plaster, bottom filled up with 1.5 to 2.5 ft. of fine sand. *Exper. No. 4.*—Canal, 800-ft. length, trapezoidal section with side slopes 2 on 1 and bottom width 8 ft., concrete lined with 1:3 mortar spread roughly, partially cleaned before measurements were made. *Exper. Nos. 5 and 6.*—Conduit, 700-ft. length, concrete lined with 1:3 cement mortar in smooth condition, grade of floor same as water surface. *Exper. No. 7.*—Canal, 1000-ft. tangent, lining of concrete without plaster, bottom free from sand and gravel, sides and bottom covered with thin coat of moss. *Exper. No. 8.*—Conduit, 1000-ft. length, lining of concrete tamped in behind boards and not plastered, several inches of sand and gravel on bottom, some moss and grass on sides.

The use of the following coefficients in Kutter's formula was suggested by the board of consulting engineers, consisting of John R. Freeman, Frederic P. Stearns and Jas. D. Schuyler: (1) For open masonry conduits of cement or smoothly plastered masonry, $n=0.018$; (2) for concrete-lined tunnels, or covered masonry conduits, $n=0.014$; (3) for steel pipe with rivet heads and seams projecting on the interior, $n=0.016$; (4) for earth canals with bottom left by dredging, $n=0.0275$.—(Eng. News, June 6, 1907.)

The Effect of Changes in Canal Cross-Sections Upon the Rate of Flow (By F. W. Hanna. Eng. News, June 6, 1907).—In the construction

of a canal it is usually necessary to provide for carrying its waters through culverts, flumes, siphons and other important changes of cross-section of waterway; and in order to compute properly its capacity, some estimate of the effects of such changes on the flow must be made. The mathematical discussion in this article deals with this problem.

A Solution of the Problem of Determining the Economic Size of Pipe for High-Pressure Water-Power Installation (By A. L. Adams. Trans. A. S. C. E., Vol. LIX).—Rule: "That pipe fulfills the requirements of greatest economy wherein the value of the energy annually lost in frictional resistance equals four-tenths (0.4) of the annual cost of the pipe line." Discussed by formulas.

The Flow of Water Through Submerged Tubes; Results of Experiments at the University of Wisconsin (By C. B. Stewart. Bulletin, Univ. of Wisconsin. Eng. News, Jan. 9, 1908).—Very extensive article with illustrations and diagrams.

A Logarithmic Diagram for the Flow of Water in Open Channels (By G. T. Prince. Eng. News, Feb. 6, 1908).

Coefficient of Discharge through Circular Orifices (Eng. News, July 9, 1908).—Tables of coefficients; also seven conclusions stated by the writer, Mr. H. J. Bilton.

Bazin's Hydraulic Formula ("Annales des Ponts et Chaussées" for the fourth quarter of 1897; Eng. News, Aug. 13, 1908).—Given in metric measure, as follows:— $v = 87\sqrt{rs + (1+m+\sqrt{s})}$, the value of m varying with the surface of the channel as follows: (1) Very smooth (cement, planed wood, etc.), $m = 0.06$; (2) smooth (plank, brick, cut stone, etc.), $m = 0.16$; (3) rough masonry, $m = 0.46$; (3a) mixed, or intermediate, very regular earth excavation, paved slopes, etc., $m = 0.85$; (4) ordinary earth channels, $m = 1.30$; (5) earth channels in bad condition, $m = 1.75$.

A diagram for Bazin's formula for flow in open channels, prepared by O. von Voigtlander, is published in Eng. News of April 15, 1909.

A Collection of Formulas for Water-Pressure and Moments in Submerged Beams (By D. N. Showalter. Eng. News, May 27, 1909).—Formulas, illustrations and tables.

Ratings of a Pitot Tube (By E. C. Murphy. Eng. News, Aug. 12, 1909).—Illustrated. Rating curve diagrams.

Huge (625 Cu. Ft. per Sec.) Venturi Meters, India (Eng. News, Nov. 25, 1909).—Illustrated.

The Use and Care of the Current Meter, as Practised by the U. S. Geol. Survey (By J. C. Hoyt. Trans. A. S. C. E., Vol. LXVI., Mar., 1910).—Illustrations and descriptions of various types of meters and recording devices, rating of meters, and methods of making hydraulic measurements.

Friction of Air in Small Pipes (By E. G. Harris. Univ. of Missouri Bulletin; Eng. Rec., Dec. 3 1910).—Experiments to determine the value of the coefficient c in the formula:

$$f = c \frac{LV^2}{rd^5}$$

in which f = loss of pressure in lbs. per sq. in.; l = length of pipe in ft.; V = the cu. ft. of free air passing per second; d = diam. of pipe in ins.; r = ratio of compression to atmospheres; c = the experimental coefficient. The result of the experiments indicated that for pipes of $\frac{1}{4}$ " to 12" in diameter the value of $c = 0.076 - 0.00188d$, so that the above formula would reduce to:

$$f = (0.076 - 0.00188d) \frac{LV^2}{rd^5}$$

63.—WATER SUPPLY.

Source and Distribution.—Water supply is derived primarily from rain, snow, hail, sleet and dew, generally termed *rainfall* or precipitation. The amount of rainfall in any locality is the depth of the precipitation in inches, when melted. In some localities dew forms no inconsiderable proportion of the total. The "dew-point" is that temperature at which the air begins to deposit (more) moisture (than it takes up). It is not a fixed temperature.

The Distribution of Rainfall and Source of Water Supply may be grouped as follows: **Rainfall**—

Run-off	{	Surface Water	{	Streams.	{	Natural (lakes).
		Reservoirs	{	Artificial.		
Evaporation.						
	{	Ground Water	{	Vegetation.		
		Saturated soil.				
Seepage	{	Underground Water	{	Galleries.		
			{	Springs.		
			Wells	{	Shallow.	
			{	Deep driven	{	Artesian.*
						Pumping.

Use in Various Branches of Engineering.—The consideration of water supply is pertinent to the sections which follow, namely,

64. Water Works.....	page 1202.
65. Sanitation.....	page 1295.
66. Irrigation.....	page 1313.
67. Waterways.....	page 1320.
68. Water Power.....	page 1332.
70. Electric Power and Lighting.....	page 1379.

Rainfall.—Engineers are concerned mainly with (1) the *average* monthly precipitation, (2) the monthly rainfall for the *driest* years, and (3) the *maximum* rates of rainfall which may be expected, in any given locality. The first two are for the consideration of Supply; the last, for Discharge.

*Mr. Myron L. Fuller, Geologist in Charge of Underground Water Supplies, U. S. Geol. Surv. (Water Supply & Irrigation Paper No. 150), states that there is much looseness in the use of the word "artesian," and great variation of its use in different parts of the country. After a careful canvass of the leading geologists of the country engaged in hydraulic studies, he has proposed the following definitions of terms:

Artesian Principle.—The hydrostatic principle in virtue of which water confined in the materials of the earth's crust tends to rise to the level of the water surface at the highest point from which water is transmitted. Gas as an agent in causing the water to rise is expressly excluded from this definition.

Artesian Pressure.—The pressure exhibited by water confined in the earth's crust at a level lower than its static head.

Artesian Water.—That portion of the underground water which is under artesian pressure and will rise if encountered by a well or other passage affording an outlet.

Artesian System.—Any combination of geologic structures, such as basins, planes, joints, faults, etc., in which waters are confined under artesian pressure.

Artesian Basin.—A basin of porous bedded rock in which, as a result of the synclinal structure, the water is confined under artesian pressure.

Artesian Slope.—A monoclinical slope of bedded rocks in which water is confined beneath relatively impervious covers owing to the obstruction to its downward passage by the pinching out of the porous beds, by their change from a pervious to an impervious character, by internal friction, or by dykes or other obstructions.

Artesian Area.—An area underlain by water under artesian pressure.

Artesian Well.—Any well in which the water rises under artesian pressure when encountered.

* Figures enclosed in parentheses are totals in inches for the 12 months, and indicate average yearly precipitation for the period of years stated in the last column.

In connection with the preceding table, the following Table, No. 2, shows in respective order the percentages of rainfall to average rainfall: *First*, for the driest year; *Second*, for the two driest years; *Third*, for the three driest years; closing with 1896.

Ex.—For Pittsburg, the average rainfall, from Table 1, is 36.59 ins. Then, using the percentages in Table 2, following, we have: *First*, for the driest year, $36.59 \times 0.70 = 25.61$ ins.; *Second*, for the two driest years, $36.59 \times 0.78 = 28.54$ ins.; *Third*, for the three driest years, $36.59 \times 0.85 = 31.10$ ins.

2.—*PERCENTAGE OF RAINFALL TO AVERAGE RAINFALL.

(To be used in connection with preceding table. See Example, p. 1194.)

<i>North Atlantic:</i>	Boston, 60, 70, 80; New Haven, 74, 78, 82; New York, 62, 77, 80; Philadelphia, 70, 75, 80; Washington, 69, 71, 74.
<i>South Atlantic:</i>	Wilmington, 75, 80, 81; Charleston, 48, 55, 62; Augusta, 81, 88, 87; Jacksonville, 74, 77, 83; Key West, 54, 61, 73.
<i>Gulf and Lower Mississippi:</i>	Shreveport, 67, 75, 75; Montgomery, 76, 80, 83; Mobile, 68, 75, 78; New Orleans, 64, 75, 77; Galveston, 50, 65, 72; Nashville, 67, 73, 83; Vicksburg, 70, 74, 83.
<i>Ohio Valley:</i>	Pittsburg, 70, 78, 85; Cincinnati, 60, 72, 71; Indianapolis, 59, 76, 82; Louisville, 74, 81, 85; Cairo, 62, 75, 81.
<i>Lake Region:</i>	Marquette, 69, 75, 81; Detroit, 65, 72, 79; Cleveland, 71, 74, 81; Duluth, 65, 81, 88.
<i>Upper Mississippi Valley:</i>	St. Louis, 55, 65, 75; Davenport, 56, 68, 73; Chicago, 66, 80, 86; Milwaukee, 66, 74, 73; Madison, 39, 58, 68; LaCrosse, 57, 78, 79; St. Paul, 53, 54, 75.
<i>The Plains:</i>	Omaha, 57, 63, 70; Dodge City, 51, 58, 73; North Platte, 56, 67, 72; Denver, 59, 71, 77; Cheyenne, 39, 62, 75.
<i>The Plateau:</i>	Yuma, 25, 50, 46; Phoenix, 52, 88, 90; Tucson, 44, 79, 80; Santa Fe, 53, 63, 66; Carson City, 57, 63, 72; Salt Lake City, 55, 64, 74; Spokane, 73, 84, 84; Walla Walla, 46, 81, 86.
<i>Pacific Coast:</i>	Astoria (average rainfall 77 ins.), 64, 68, 77; Portland, 67, 76, 79; Red Bluff, 52, 64, 58; Sacramento, 42, 67, 84; San Francisco, 51, 73, 78; Los Angeles, 33, 48, 59; Fresno, 61, 65, 74; San Diego, 30, 54, 61.

High Intensities of Rainfall.—Flood discharges in rivers, creeks, sewers, etc., naturally occur at times of high intensities of rainfall, and hence it is important to know, for particular localities, the maximum rates of downpour which have been recorded, and which are liable to take place in the future. Considerable confusion has arisen as to the meaning of the various terms "intensity of rainfall," "maximum rate of rainfall," etc.: for even a single shower has various intensities of downpour, while the recorded "intensity" often comprises the ratio of the total downpour to the total time, omitting, perhaps, the critical data most desired for the design of the sewer, namely, a higher intensity of downpour for a shorter period of time, during the shower. In order to clarify this subject, the following notation is used:

Let d = the depth of rainfall in ins., for any given time T in hrs.;
 T = time in hours corresponding to depth of precipitation d in ins.;
 r = average rate of downpour in inches per hour during the whole

shower = $\frac{d}{T}$, designating the length of time by a sub-numeral in the denomination of hours, thus—

$r_{.4} = \frac{d}{T} = \text{say } \frac{4}{4} = \text{average rate of downpour during the whole 4 hours of the shower;}$

$i = \text{maximum average rate of downpour in inches per hour during a protracted period of highest intensity} = \frac{d}{T}$, designating the length of time by a sub-numeral in the denomination of hours, thus—

$i_{1.5} = \frac{d}{T} = \text{say } \frac{3}{1.5} = \text{maximum average rate for 1.5 hours;}$

$I = \text{maximum maximum rate of downpour in inches per hour during the short time or greatest intensity} = \frac{d}{T}$, designating the length of time by a sub-numeral in the denomination of hours, thus—

$I_{0.25} = \frac{d}{T} = \text{say } \frac{75}{.25} = \text{highest intensity, for } \frac{1}{4} \text{ hour.}$

* Abstract from Table No. 6, "Public Water Supplies" by Turneure and Russell: John Wiley & Sons, 1901. Although not strictly applicable to preceding table closing with 1904, these percentages may be used with fairly good results. Published by permission.

Thus, from the above, say for any given shower, we have the complete data: $r_4 = 1$, $i_{1.5} = 2$, $I_{0.25} = 3$. This means that it rained 4 ins. in 4 hours., or at the average rate of 1 in. per hour; 2 ins. per hour for 1.5 hours of greatest downpour; and 0.75 in. in 15 minutes, or at the rate of 3 ins. per hour for the short period of greatest intensity. In current literature it is often problematical whether r , i or I is intended as the rate of downpour.

FORMULAS FOR MAXIMUM INTENSITY OF DOWNPOUR, i .

NOTATION.

i = average rate of downpour in ins. per hour for the time t in mins.;
 t = time or duration of downpour in minutes.

FORMULAS.

A. N. Talbot's "Maximum" formula for Eastern U. S*.

$$i = \frac{360}{t + 30} \dots \dots \dots (1)$$

A. N. Talbot's "Ordinary" formula for Eastern U. S*.

$$i = \frac{105}{t + 15} \dots \dots \dots (2)$$

E. Kushling's formula for New York City and vicinity:

$$i = \frac{120}{t + 20} \dots \dots \dots (3)$$

†C. W. Sherman's formula for Eastern U. S., when $t < 180$:

$$i = \frac{420}{t + 30} \dots \dots \dots (4)$$

But when $t > 180$ the value of i is too small.

†C. W. Sherman's "Maximum" formula for Boston:

$$i = \frac{38.64}{t^{0.687}} \dots \dots \dots (5)$$

†C. W. Sherman's "Ordinary" formula for Boston:

$$i = \frac{25.12}{t^{0.687}} \dots \dots \dots (6)$$

E. S. Dorr's "Ordinary" formula for Boston:

$$i = \frac{150}{t + 30} \dots \dots \dots (7)$$

Standard Rain Gage.—For a complete description of the measurement of precipitation, see Weather Bureau Paper "W. B., No. 285" U. S. Dept. of Agriculture, by C. F. Marvin, 1903, from which the following cut (standard 8-in. gage) is reproduced. *A* is the receiver; *B* the overflow attachment; *C* the measuring tube; *D* the measuring stick. The diameter of the receiving tube *a* is just 8 ins. ($8^2 = 64$) and of the measuring tube *C* is 2.53 ins. ($2.53^2 = 6.4$); hence the rainfall is magnified in the latter 10 times, which facilitates accurate measurement. The measuring stick *D* is a strip of straight-grained cedar 0.08 in. thick, 0.5 in wide, and 24 ins. long. When the tube *C* is full it overflows at *d* into *B*, and is later poured into *C* and measured. If the precipitation is snow or hail it is melted before measuring. Snow will occupy from 7 to 34 times its depth melted.

Fig. 1.—Rain Gage.

* Territory east of the Rocky Mountains.

† See Trans A. S. C. E., Vol. LIV, pp. 178 and 212.

3.—MAXIMUM RATES OF RAINFALL BY PRECEDING FORMULAS.

For periods of time ranging from 5 minutes to 3 hours.

[Rates of downpour in inches per hour for time t .]

Formula.	Duration or time of Downpour.				
	$t = 5m.$	$t = 10m.$	$t = 30m.$	$t = 60m.$	$t = 180m.$
(1) $i = \frac{360}{t+30}$ Talbot's maximum; for Eastern U. S.	8.57	7.50	5.00	3.33	1.43
(2) $i = \frac{105}{t+15}$ Talbot's ordinary; for Eastern U. S.	5.25	4.20	2.33	1.40	0.54
(3) $i = \frac{120}{t+20}$ Kuahling's; for N. Y. City and vicinity.	4.80	4.00	2.40	1.50	0.60
(4) $i = \frac{420}{t+30}$ Shermans; for Eastern U. S., when $t < 180$.	12.00	10.50	7.00	4.67	2.00
(5) $i = \frac{38.64}{\rho.657}$ Sherman's maximum; for Boston.	12.79	7.94	2.73	2.32	1.09
(6) $i = \frac{25.12}{\rho.657}$ Sherman's ordinary; for Boston.	8.31	5.16	2.43	1.51	0.71
(7) $i = \frac{150}{t+30}$ Dorr's ordinary; for Boston.	4.29	3.75	2.50	1.67	0.71

Note.—To obtain the total depth of rainfall for the duration of time t

given: Multiply the rates or intensities i given in the table, by $\frac{t}{60}$ ($= T$, the time in hours); thus, from formula (3) the total rainfalls which it is possible to expect in 5-, 10-, 30-, 60- and 180 minutes of downpour are, respectively, $4.80 \times \frac{5}{60} = 0.4$ in., $4.00 \times \frac{10}{60} = 0.67$ in., $2.40 \times \frac{30}{60} = 1.20$ in., $1.50 \times \frac{60}{60} = 1.50$ in., and $0.60 \times \frac{180}{60} = 1.80$ in. In calculating the maximum rate of discharge

from a catchment area into a stream or sewer, it is necessary to estimate the time required for the rain to reach such outlet, say 30 minutes, more or less, for sewers, and a longer time for streams, generally. See *Run-off*, below.

Run-off.—The term "run-off" is rather indefinite, but in general it may be defined as the surface discharge from a catchment area or basin. Each stream has its catchment area. The discharge from a stream may be estimated in three ways:

1st. By Kutter's formula (p. 1167), with sectional area, mean radius and hydraulic slope known;

2nd. By actually gaging the stream (see page 1182, etc.);

3rd. By estimating the percentage of run-off to total rainfall.

All three methods should be used if possible, for checking.

Formulas for run-off are founded on actual stream gagings, but must be used with care for the following reasons:

(a). Each stream, strictly speaking, should have its own run-off formula (or formulas—see b , c and d).

(b). The run-off increases with the amount and *intensity* of rainfall.

(c). It is greater in the spring, when the ground is frozen and the snows are melting, than during the summer.

(d). It may vary considerably at different points in the same stream, the variation being due almost wholly to seepage discharge or influx from springs.

(e). The run-off varies generally with the compactness of the soil and sub-soil, being very slight in sand.

(f). It is influenced more or less by the slope of the catchment basin (contrary to some authorities).

In addition to the above, it is to be noted that the *time* of run-off affects largely any water proposition. If the run-off is immediate the waters usually

have to be stored unless the supply is very much in excess of the demand. Storage may obtain in several ways, namely, (1) by high altitude of the catchment basin, delaying the melting of the snow; (2) by forest growth in the catchment basin, decreasing evaporation; (3) by natural lakes in the catchment area; (4) by artificial storage reservoirs; (5) by sub-soil storage.

Sub-surface flow accompanies every stream and may be considered part of the run-off, under certain circumstances, if readily available. It is not included in ordinary stream measurements, but may be detected in "dry" streams by digging test pits. It may be brought to the surface and become available by the construction of tight coffer-dams extending to bed rock, or by the construction of ordinary dams with tight foundation. Many creeks apparently "dry" in summer may thus be made to yield a considerable discharge.

Formulas for Run-off.—The following notation is for the subjoined formulas:

a = area of catchment basin, in acres;

A = area of catchment basin, in square miles;

d = precipitation on catchment per month, in inches;

D = total precipitation for any period, in inches;

c = coefficient of discharge;

q = discharge in cu. ft. per second per square mile of catchment for precipitation d .

Q = total discharge in cu. ft. per acre of catchment for precipitation D .

Then for total run-off per acre of catchment,

$$Q = c \cdot \frac{D}{12} \cdot 43560 a = 3630 c D a \dots\dots\dots (1)$$

in which c may vary from 0 to 100; almost always between 0.05 and 0.75; generally between 0.20 and 0.60; rough average 0.40. (But see page 1197.) The value of c in formula (1) can usually be derived from the coefficient for some other catchment, near the locality, for which the run-off has been

gauged. Then, by transposition, $c = \frac{Q}{3630 D a}$. The accuracy of this method

is enhanced more or less if the two catchments are very dissimilar in character of soil, geology, topography, area, etc. It is far superior however to any blind assumption of percentage based on averages in distant localities.

The monthly discharge may be obtained by substituting d for D in formula (1).

Dicken's formula assumes the maximum discharge q_{max} in cubic feet per second to be proportional to $\sqrt{A}$; thus,

$$q_{max} = c' \sqrt{A} \dots\dots\dots (2)$$

in which c' is a coefficient depending upon rainfall, character of soil, topography, geology, etc. The value of c' in formula (2) may often be obtained from similar catchments in the same locality, in about the same manner as described for c in formula (1). When c' is known this formula is useful in approximating the flood discharge from a catchment for the design of wasteways for dams.

The writer has seen it stated repeatedly that run-off is independent of the degree of slope of the catchment area. But his experience and investigations are to the contrary. Both the declivity of the ground surface and its geological formation have considerable effect on the time and amount of run-off, especially if measured near the headwaters of the effluent stream.

Run-off formulas must be used with great caution and only in connection with gagings of streams, unless the merest approximation is desired. Even then the gagings should cover a long period, by months, for a number of years, as the precipitation varies from year to year in both amount and intensity, greatly affecting the run-off. In general, the records of 20 years are desirable if the demands approach closely the minimum annual supply. The minimum as well as the average discharge should be sought. Much valuable data relating to discharge of streams may be obtained from the Water Supply Papers issued by the U. S. Geological Survey, Dept. of the Interior.

For a good discussion of an additive method of computing run-off to sewers, see article in *Eng. News* of March 11, 1909, from Paper by Carl H. Nordell.

Evaporation.—Evaporation is a physical change from a solid or liquid to a vaporous or gaseous state. It is primarily due to heat. All substances emit vapors to a greater or less extent, depending largely upon the temperature and also upon many other conditions, including humidity.

Evaporation from Ice and Snow takes place at *all temperatures*. The mean evaporation from the surface of ice may be assumed at about 0.04 in., and from snow at about 0.02 in., per day of 24 hours.

Evaporation from Water surface goes on continually day and night, at all temperatures. But when the temperature is below the dew-point the additional moisture from condensation may more than offset the loss due to evaporation. The rate of evaporation increases with—

- (1) Temperature of water surface;
- (2) Dryness of air at water surface;
- (3) Velocity of the wind at water surface.

The maximum evaporation from surface of running water exposed to hot sun and dry, hot wind in the tropics may reach 0.50 inch per day of 24 hours. But in the southern part of the United States it will rarely if ever exceed 0.40 inch per day. The average rate of evaporation from water surface of reservoirs during the summer months may be assumed safely not to exceed 0.35 inch per day in the south and southwest, and 0.18 inch in the northern states, unless the reservoirs are unusually exposed or shallow. The average rate per day for the year may be assumed at about one-half these figures, that is, 0.18 and 0.09 inches respectively. Running water evaporates more rapidly than still water; and water in a shallow pan, exposed to the sun, will evaporate more rapidly than in a reservoir.

In a catchment basin the evaporation from the land surface continues only for a definite period after each shower until the land dries, unless there is vegetation in which case it continues at a greater or less rate. Evaporation from a meadow of luxuriant grass has been found to be two or three times as rapid as from a still water surface.

4.—MONTHLY EVAPORATION IN INCHES IN THE UNITED STATES FROM WATER SURFACES (APPROXIMATE).

South Pacific Coast.....	3.3	2.5	2.8	3.9	4.1	4.5	5.4	5.7	4.5	5.0	3.3	3.0	48

Note that the above table shows *increasing* evaporation toward the *South* for any section where conditions other than temperature are about equal. Evaporation is *less* in regions adjacent to *large bodies of water* (as the Atlantic, Pacific and Great Lakes regions) for the same latitude, because there is greater humidity in the atmosphere. Conversely, it is to be noted that the great dry plateau region in the West furnishes the greatest evaporation. Evaporation on the North Pacific Coast is low because of the almost incessant rains for six months of the year. But south of Oregon the Pacific Coast shows greater evaporation than the Atlantic Coast of the same latitude, because of dryness of the atmosphere and higher mean temperature.

Seepage.—The seepage in a catchment area is equal to the total rainfall minus the run-off and evaporation. When the ground is frozen the seepage is practically naught, while in deep, sandy soil it may equal nearly the total precipitation. It is usual to estimate the seepage and evaporation together as the *total loss* in a catchment, reservoir, stream or canal. If the latter has locks or gates, leakage is also included. The loss due to seepage and evaporation combined, for a canal in an earthen bed, will vary generally from $1\frac{1}{2}$ to $2\frac{1}{2}$ inches per day, depending upon size of canal, character of soil, etc. The rate of seepage often decreases with the age of the canal, as the fine particles pack into the soil bed and decrease the voids. Experiments with models have shown that the ratio of annual seepage to annual evaporation for total rainfall (with no run-off), in temperate climates is, for earth bed, about 1 : 2.4; and for sandy bed, about 5 : 1. These figures, however, cannot apply to reservoirs and canals where the process of evaporation is continuous, which was not the case with the experiments. Roughly speaking, the comparative rates of seepage in various soils is about as follows, assuming that for sandy soil to be unity: Minute gravel, 100; coarse sand, 10; fine sand, 2; sandy soil, 1; sandy clay, 0.5; clay, 0.25 to 0.00.

Mr. Elwood Mead states* that the loss from seepage and evaporation as determined from a large number of measurements made by the U. S. Dept. of Agriculture, was 2.47 per cent per mile in 1900, and 1.45 per cent per mile in 1901—grouped as follow:

Capacity of Canals.	Loss per mile. Per cent.
(a). Canals carrying 100 cubic ft. per second or more.....	0.98
(b). Canals carrying between 50 and 100 cu. ft. per second.....	2.67
(c). Canals carrying between 25 and 50 cu. ft. per second.....	5.22
(d). Canals carrying less than 25 cubic feet per second.....	7.48

It is interesting to note here that the above table may be generalized by the following law: The total loss per mile for canals carrying from 25 to 200 cubic feet per second was, in 1900 and 1901, from 1.9 to 2.0 cubic feet per second.

From evaporation alone it is probable that the loss rarely exceeds 1 per cent per mile in irrigation canals, when the velocity is $2\frac{1}{2}$ to 3 feet per second. Reservoir losses from the same cause may vary from 2 to $7\frac{1}{2}$ feet in depth, annually; generally from 3 to 5 ft.; rough average, 4 ft. (see Table 4, preceding page).

EXCERPTS AND REFERENCES.

Relation of Rainfall to Runoff in California (By J. B. Lippincott and S. G. Bennett. Eng. News, June 5, 1902).—The following basins are discussed: Sacramento River Basin, San Matea Creek, Salt Springs Valley Watershed, Stanislaus River Basin, Tuolumne River Basin, San Joaquin and Kings River Basin, Mojave River, Cuyamaca Reservoir Watershed, Sweetwater Reservoir Basins. A diagram shows the annual and mean runoff from the above watersheds. A table gives the number of "acre-ft. per sq. mile" for "depth of runoff in ins." for depths advancing by hundredths of an inch up to one inch. The table is based on 1" depth of runoff = 53½ acre-ft. per square mile = 640 ÷ 12.

64.—WATER WORKS.

This subject is treated under five main headings, as follows:

A.—Consumption of Water.....	Page 1202.
B.—Purification of Water.....	Page 1204.
C.—Reservoirs.....	Page 1205.
D.—Conduits.....	Page 1207.
E.—Distributing System.....	Page 1280.

A.—CONSUMPTION OF WATER.

The "consumption" of water in cities and towns is measured in gallons per capita per day, of population supplied,* and includes the total amount of water "used" and *wasted*. The amount of water actually needed for domestic supply could undoubtedly be restricted to 20 gallons per capita per day, but there is a great deal of careless and wanton waste, as well as use for fire protection, manufacturing purposes, etc. Roughly speaking, it is customary to estimate the probable consumption at 50, 60 or 80 gallons for small cities and towns about to be supplied, and based on a population 20 years in the future. For large cities, see Tables 1 and 2 following.

Water meters are most frequently used in connection with manufacturing plants; and where water is not plentiful they are useful in restricting undue waste in domestic supply, otherwise they should be omitted, as a free use of water promotes cleanliness.

* Data in Tables 1 and 2 up to the year 1890 are from Paper No. 758 of Trans. A. S. C. E., Vol. XXXIV, entitled "Consumption and Waste of Water" by Dexter Brackett. From 1890, the data have been gathered by the writer, from official sources.

B.—PURIFICATION OF WATER.

The purification of water for domestic use has received considerable attention in the United States during the past 15 or 20 years, and in Europe for a much longer period. Speaking generally, there are three main steps in the purification of surface water, from streams or reservoirs, namely, (1) screening; (2) sedimentation; (3) filtration. The last named is often omitted.*

Screening.—At the approach to the intake end of the pipe there should be placed a grating composed of vertical bars of wood, iron or steel to screen out the leaves and prevent the drift generally from entering the pipe. These bars are placed edgewise to the direction of flow and are stayed laterally by small rods and fillers.

Sedimentation.—The screened water is next allowed to pass into a settling basin of greater or less capacity to deposit, while at rest, the sedimentary matter which it held in suspension while in an agitated state. Turbid waters, those suspending sand, silt and clay, should necessarily thus be treated. If the particles of clay are minute, that is, as fine or finer than bacteria, it becomes necessary to add a coagulant to the water before it enters the basin. Various compounds of alum, lime and iron are used as coagulants. Perhaps sulphate of alumina is the most common. If a fair amount of coagulant is used, the time required for sedimentation will be about 24 hours, depending upon various conditions. It is to be noted that sedimentation with coagulation may be efficient in removing not only the fine particles of suspended matter above referred to, but a large percentage of bacteria as well.

Settling basins may be single or multiple and provided for continuous or intermittent flow.

"Slow" Sand Filtration.—This is essentially the so-called English system, having been employed almost exclusively in England since the early part of the Nineteenth Century. The filter beds consist of one or more water-tight reservoirs each with an area of 10,000 to 80,000 square feet. On the bottom of each reservoir is laid a system of drains for carrying off the filtered water. The materials composing the beds proper are broken stone, gravel and sand, placed in successive layers and graduated to size, with the coarser material at the bottom. The top bed of sand usually varies from 24 to 60 inches in thickness and should be composed of fine grains of uniform size.

The rate of filtration usually averages from 6 to 9 feet of water column per day of 24 hours with good results. Care must be used to see that the drains carry off the filtered water freely. The water may be delivered to the filter beds by gravity or by pumping. If it contains much sediment it should first be passed through the settling basin as previously described under Sedimentation. Two systems are employed—the continuous and the intermittent.

The result of sand filtration when highly efficient is to remove from the water its impurities and render it potable. These impurities are injurious bacteria, vegetable organic compounds (sometimes coloring the water highly) and animal pollution, as sewage. The last named is the most easily removed. A good sand filter usually removes from 98.5 to 99.5 per cent of bacteria. To eliminate vegetable organic coloring effectively, coagulants are employed—compounds of lime, alum, iron, etc.

During filtration a thin film forms on the surface of the sand and acts as a fine strainer, collecting most of the bacteria and other impurities. Although the process is (purely?) mechanical in theory yet it is a fact that water is often rendered purer *chemically* by having passed through the filter. The oxygen of the air (and of the water) is the great purifier.

"Rapid" Sand Filtration.—This system is distinctly American and is generally termed "mechanical" filtration. Mechanical filters are patented

*Another process, the Copper Sulphate treatment, is being used considerably where algae is present in the water. Many articles descriptive of copper sulphate as an algicide, for reservoir treatment, etc., have appeared in current technical literature during the past ten years; also, of sulphate of alumina, hypochlorite of lime, etc.

devices for increasing the rate of filtration, by agitating the sand mechanically or by compressed air, and by the use of coagulants. They have generally given satisfaction and bid fair under many conditions to compete with ordinary sand filters in beds. The first cost of mechanical filters is less than for sand filters, but the cost of operation is greater.

C.—RESERVOIRS.

Reservoirs may be classed as follows:

- (a) Storage Reservoirs, comprising large natural basins with dam (see Dams, page 844), and wasteway constructed at outlet.
- (b) Distributing Reservoirs (artificial) constructed in earth by excavation and embankment, with paved inner slopes:
 - High-service reservoirs;
 - Low-service reservoirs.
- (c) Stand-Pipes or water towers of steel, reinforced-concrete or wood.

(a) **Storage Reservoirs*** of greater or less extent are commonly to be had on most running streams, generally near the source. At the lower end of the natural basin and at a contracted point of the out-flowing stream, as in a canon, the dam is constructed of sufficient height to guarantee a storage supply sufficient for the dry or summer months. If the supply is for domestic use the storage will be estimated in millions of gallons; if for irrigation it will be estimated in acre ft. (one acre-foot = 43,560 cubic feet); if for water power it will be estimated in cubic feet or millions of cubic feet.

(b) **Distributing Reservoir** sites should be selected with great care. A side-hill location should be examined very carefully for any indications of sliding land, a serious condition for reservoir construction. A slide usually reveals a wet or marshy spot at its upper end. The water collects there, filters to an inclined sub-stratum (generally clay) and by moistening or lubricating it the coefficient of friction is reduced to such an extent that sliding takes place. If, unfortunately, it is discovered that a reservoir has been constructed on such a slide, the hill-side above and around the reservoir should be sub-drained thoroughly at the sliding plane to keep it as dry as possible.† This sub-drainage may be accomplished by driving small tunnels, with branches, and laying drain tile to carry away the water.

Distributing Reservoirs situated immediately at the townsite are convenient and economical. Incidentally they serve as secondary settling basins, and hence provision should be made for "blowing" them out whenever the bottoms accumulate much sediment. The waste pipe leads from a depression in the bottom of the reservoir, and small water pipes are laid for occasional washing and cleansing. Economically, distributing reservoirs serve to lower the static head on the distributing system of pipes through the town, by receiving the supply direct, through the pressure-pipe line, from the storage reservoir or headworks. By this means the pressure on the system may often be reduced several hundred feet. If, however, the storage reservoir is not at too high an altitude the pressure-pipe line may be connected directly with the mains and allowed to discharge into them, but usually only in case of fire when high pressure is needed. The high-service and low service reservoirs are primarily designed to supply the high and the low sections of the town, respectively, each connected with its own distributing system.

It is to be noted that considerable power for lighting and pumping can be developed at the distributing reservoirs by utilizing the available head from the source above. By this means water may be pumped to a stand-pipe for supplying an isolated section of the town at considerable elevation and distance.

The outlet pipe from a reservoir should be so arranged that water may be taken at different elevations above the bottom of the reservoir, in order to avoid suspended matter and sediment.

* See Paper entitled "Lake Cheesman Dam and Reservoir" by Messrs. Harrison and Woodard, in *Trans. Am. Soc. C. E.*, Vol. LIII (Dec., 1904) p. 89, for a very complete description of a typical storage reservoir, with construction of dam, wasteway, outlet, etc.

† See Paper entitled "A Phenomenal Land Slide" by D. D. Clarke, in *Trans. Am. Soc. C. E.*, Vol. LIII (Dec., 1904), page 322.

Reservoir Linings.—The bottom may be lined with 6 inches or more of concrete laid with expansion joints; on this, from $\frac{1}{2}$ to $\frac{3}{4}$ inch of cement mortar; next, a coat of liquid asphalt; and finally, a harder coat of asphalt. The side slopes may be lined with 6 inches or more of concrete laid with expansion joints; a coat of asphalt; a layer of brick dipped in hot asphalt and laid flat; and then a finishing coat of asphalt, filling up all the joints. Instead of the brick lining, a coating of asphalt or asphalt cement is sometimes employed. Expansion joints are spaced from 10 to 20 feet, depending upon the climate.

It is generally advisable to discharge the water into the reservoir through an aerating fountain.

(c) **Stand-Pipes** are simply upright riveted steel pipes with the lower end capped, resting on a foundation usually of concrete, and thoroughly anchored. The plates, joints and rivets will have to resist various complicated stresses if the stand-pipe is in a freezing climate:

(a) For static pressure, $t = \frac{0.434 h r}{e f}$ [See notation below.].....(1)

(b) If the water at surface of tank is frozen and pumps are acting to force water into the tank there is an *added pressure* which would have to be reduced to equivalent head.

(c) Or, if the water subsides from the ice there is a *minus pressure* produced by the resulting vacuum, which may tend to collapse the tank.

(d) The wind pressure is a very considerable item which has to be reckoned within the design of large stand-pipes. The resisting moment M_s' in inch-lbs., for a cylindrical section of stand-pipe, due to bending, is

$$M_s' = \frac{I l}{y} = f \pi r^2 t e \dots\dots\dots(2)$$

where f = allowable fiber stress in lbs. per sq. in.;
 I = moment of inertia of cross-section, in ins.;
 y = radius of pipe or tank, in ins.;
 π = 3.1416;
 t = thickness of metal shell, in ins.;
 e = efficiency of riveted joint, say 0.50 to 0.80.

But the bending moment M_s' in ft.-lbs., is

$$M_s' = \frac{6P}{10} \cdot \frac{d h^2}{2} \dots\dots\dots(3)$$

where P = wind pressure in lbs. per sq. ft for *flat* surfaces;

$\frac{6P}{10}$ = wind pressure in lbs. per sq. ft for cylindrical diameters;

d = diameter of tank, in feet;

h = depth of section considered, in feet, below top of tank.

Equating the resisting moment (2) with the bending moment (3), multiplying the latter by 12 to reduce to inch-lbs., we have

$$f \pi r^2 t e = 3.6 P d h^2 \dots\dots\dots(4)$$

whence $f = \frac{3.6 P d h^2}{\pi r^2 t e} = \frac{4.6 P h^2}{d t e} \dots\dots\dots(5)$

and if P is taken at 50 lbs. per sq. ft., we have

$$f = \frac{230 h^2}{d t e} \dots\dots\dots(6)$$

and $t = \frac{230 h^2}{d f e} \dots\dots\dots(7)$

(e) In order to provide for possible corrosion, the calculated thickness of shell may be increased by say $\frac{1}{16}$ in., as with riveted steel water pipe. It should be noted that the thickness of shell at top of tank should not be less than $\frac{1}{4}$ inch.

A common method employed in the design of stand-pipes is to calculate for static pressure (a), wind pressure (d), and allow for corrosion (e). If soft steel is used, with an ultimate strength of 60,000 lbs., f may be taken at

15,000 lbs. where no freezing is expected. But otherwise this should be reduced to 12,000 or 10,000 lbs., depending upon the climate. The tank should be well stiffened against collapse.

An Elevated Tank is a tank supported at an elevation, usually on tower posts, hence the name water-tower. The whole structure is sometimes enclosed in a circular masonry shell.

Stand-pipes and elevated tanks are more economical in certain localities than are ordinary reservoirs. They are useful in furnishing a supply to districts where the population is small or isolated; or to sections above the altitude of the main reservoirs. They are often used in towns equipped with the direct pumping system, to provide safe pressure in case of fire; and are connected with the main line, as close to the pumping station as possible.

D.—CONDUITS.

After the water has been purified to a greater or less degree at the Headworks by *sedimentation* and perhaps by *filtration*, it is delivered by the *conduit* to the high- or low-service reservoirs or to stand-pipes, situated as near the town as proper altitude and selection of site will permit.

Conduits (or aqueducts) may be classified as follows:

- I. Open conduits, or those which follow the hydraulic grade line.
 - (a) Canals.
 - (b) Flumes.
- II. Closed conduits which follow relatively the hydraulic grade line.
 - (a) Bored wooden pipe, not banded.
 - (b) Salt glazed vitrified pipe.
 - (c) Masonry aqueducts, including cement pipe.
- III. Pressure pipe lines.
 - (a) Bored wooden pipe, banded.
 - (b) Wood stave pipe (banded).
 - (c) Cast iron pipe.
 - (d) Wrought iron pipe.
 - (e) Steel pipe.
 - (f) Attachments.
 - (g) Specials.

Ia.—CANALS.

Where the topography will admit, considerable saving of cost may often be made by employing open channel construction from the headgate to the settling basin instead of the more expensive pipe-line construction usually adopted. But the sanitation must also be considered, as well as the possibility of freezing.

Ib.—FLUMES.

Wooden flumes may be substituted for canals (above) for small towns where a cheap construction is desired, as in the West. Flumes may be V-shaped, rectangular, or semi-circular (see Irrigation, page 1317). It is to be noted that no *open* conduit construction is to be allowed below the point where the water is purified. Steel flumes are usually semicircular.

IIa.—BORED WOODEN PIPE.

Bored Wooden Pipe has been used to a small extent in the West in certain localities where timber is cheap. Its use, however, has been confined mainly to the smaller sizes, say 6 inches or less in internal diameter. Joints are made by using wooden or cast iron hubs to couple the connecting ends. When not banded they are seldom subjected to very much static pressure. The writer has seen specimens of bored pipe 5 inches in diameter which had been removed after being in service about 40 years.

IIb.—SALT GLAZED PIPE.

Salt Glazed Vitrified Pipe is specially adapted to economic construction on small work where the topography of the ground will admit of the pipe line being laid fairly close to the hydraulic grade line, and where the static pressure is inconsiderable. It has been used successfully up to 30 inches in diameter.*

* See paper read before Am. W. W. Ass'n at Cleveland, O., April 7, 1888, by Mr. Stephen E. Babcock.

IIc.—MASONRY AQUEDUCTS.

Masonry Aqueducts are particularly economical in conveying large supplies of water under little or no pressure. Various shapes of section are used, as circular, egg shape, rectangular with arch, and tunnel shape. The first and last named are typical of the New Croton aqueduct, the circular section being 14 feet in diameter. The ordinary section is shaped like a horse-shoe resting on an inverted arch. Rubble masonry, concrete and brick are variously employed, the first named being confined to the side walls, and the last named to the lining. The brick lining is laid generally in one, two or three layers. Concrete may replace the rubble and brick to a greater or less extent. Reinforced concrete is used for high pressures.

Fig. 1.—Reinforced Concrete Aqueduct.

Fig. 1 is a section of reinforced concrete aqueduct for the City of Mexico J. D. Schuyler, consulting engineer (see *Eng. News*, April 19, 1906).

IIIa.—BORED WOODEN PIPE, BANDED.

Bored Wooden Pipe (IIa) if Banded may be used under pressure, but it should be avoided generally for better construction. The cheaper form of banding is by spiral wound wiring.

IIIb.—WOOD STAVE PIPE.

Wood Stave Pipe has had a variable reputation and has been the subject of much discussion among engineers. The writer has laid a great

Fig. 2.

Fig. 2a.

many miles of this pipe and can recommend it for cheapness of first cost and for carrying capacity. But it yet remains to be demonstrated to what

tent it will compare in economy with other kinds of pipe when its lasting qualities are better known.

Fig. 2 shows a half-section of stave pipe with staves, tongues, band with head, nut and washer) and shoe. Fig. 2a is a view of an ordinary shoe showing the saw-kerf at one end, and the metallic tongue inserted at the other. On the nearest edge is shown a beaded projection by the planer on the finished stave to insure water-tightness, but as this is subject to injury it is often omitted. Note that the tongue projects somewhat beyond either edge of the stave and is embedded in adjoining staves when the pipe is cinched tightly. The metallic tongues are usually, but not always, galvanized before being placed in the pipe. Fig. 3 is a plan

Fig. 3.

3/4-inch band (upset) with head, nut and washer. Note that the upset is very long to allow for proper cinching, and that the length is "under head." Bands should be protected from rust before the pipe is back-filled. A common method in the West is to dip them in hot asphalt after bending. Bending and dipping plants may be erected on the ground where the pipe is laid if the work is of considerable magnitude; otherwise they should be the mill ready for laying. Fig. 4 illustrates the ordinary malleable shoe or coupling for the bands, and explains itself.

Fig. 4.

Table 3, following, was prepared by the writer some years ago, and may be found useful to those who desire to make estimates on wood stave construction.

The first five items are dimensions of finished staves (see Fig.).

NOTES ON TABLE 3, PRECEDING.

Thickness of staves given is the maximum. Some engineers limit the thickness to 2 ins. even for the large sizes of pipe.

Staves can be planed readily by grinding the blades of the sticker to the proper shapes.

Sizes of rough staves are merchantable. The lumber must be clear and seasoned without checking, and *before planing*, otherwise the subsequent shrinkage will greatly affect the finished diameter of pipe.

The metal tongues should be galvanized smoothly and evenly to prevent leaky pipes; but are sometimes left plain.

Length of band may be obtained from following formulas:

For angle shoes, $L_1 = \pi (D + 2t + \frac{d}{2}) + d + \text{upset length} - \frac{1}{2}$.

For double shoes, $L_2 = \pi (D + 2t + \frac{d}{2}) + 2(d + \text{upset length} - \frac{1}{2})$.

in which L_1 = length of single band under head, in ins.

L_2 = total length of double band under head, in ins.,

π = 3.1416,

D = internal diameter of pipe in ins.,

t = thickness of stave in ins.,

d = diameter of band in ins.,

Care must be used in ordering bands. It is better to have them a little long than short. Wood stave pipe is apt to form up with a diameter from $\frac{1}{8}$ " to $\frac{1}{4}$ " too large, which must be taken into consideration when ordering hands.

Bands are proportioned to not exceed a hydrostatic-pressure stress of 15,000 lbs. per sq. in. Small bands, especially on pipes of small diameter, are apt to crush the wood, hence a lower stress than 15,000 is assumed to meet this contingency, in necessary cases, as shown by the preceding table.

4.—DISCHARGE IN MILLION GALLONS PER 24 HOURS THROUGH WOOD STAVE PIPE. NEW, CLEAN AND IN FIRST-CLASS CONDITION.

(Value of roughness $n = .010$)

[Million Gallons per 24 Hours.]

Grade or Slope s.	Diameter of Pipe, in Inches.								
	12	16	20	24	30	36	48	60	72

.010	3.07	6.71	12.30	20.10	36.30	59.30	127.0	230.0	371.0
.016	3.88	8.50	15.50	25.40	46.00	75.10	161.0	291.0	469.0
.020	4.34	9.49	17.40	28.40	51.40	83.90	180.0	325.0	534.0

Note.—For designing ordinary wood stave pipe lines it is safer to use a coefficient of roughness $n = .0105$ (Table 3) rather than .010 as above. Compare discharges in Table 4 with those in Table 3.

IIIc.—CAST IRON PIPE.

Cast Iron Pipe is more durable than wood-stave, wrought-iron, or steel pipe, but its first cost is greater for the ordinary sizes required in a pressure-pipe line or in a distributing system. It especially commends itself for use in large cities where the increased first cost can be borne easily; also for certain portions of any pipe line demanding fairly permanent construction, that is, where cost of renewal would be excessive; and generally where "specials" are required. Before deciding on the kind of pipe to

use, chemical analyses should be made of the soil and the water, and the question of electrolysis also should be considered. Cast iron pipe should be dipped in hot coal tar or asphalt or a mixture of the two before being laid in the ground.

Formulas for Designing Cast Iron Pipe are numerous, but they all agree in taking into consideration (1) the static pressure, (2) water ram, and (3) liability to breakage from rough handling before and during the laying.

NOTATION.

- t = thickness of pipe shell, in inches;
 d = inside diameter of pipe, in inches;
 h = pressure head in feet ($= 2.304 p$);
 p = pressure of water, in lbs. per square inch ($= 0.434 h$);
 p' = allowance for water ram, in lbs. per square inch;
 r = internal radius of pipe, in ins.;
 s = allowable tensile stress, in lbs. per square inch;

Based on a factor of safety of 5, s is assumed at 3,200 to 3,600 lbs.

For static pressure alone, we have,

$$t = \frac{pd}{2s} = \frac{0.217 h d}{s} \dots\dots\dots (1)$$

Practical working formulas are as follows:

Formula used by Metropolitan Water-works, of Boston:—

$$t = \frac{(p + p')d}{2s} + 0.25 = \frac{(0.434 h + p')d}{6600} + 0.25 \dots\dots (2)$$

assuming $s = 3300$. Allowances for water ram are—

$p' = 120$ lbs.	(277 ft. hd.)	for $d = 3$ to 10 ins.;
$= 110$ "	(254 " "	" $d = 12$ or 14 ins.;
$= 100$ "	(231 " "	" $d = 16$ or 18 ins.;
$= 90$ "	(208 " "	" $d = 20$ ins.;
$= 85$ "	(196 " "	" $d = 24$ ins.;
$= 80$ "	(185 " "	" $d = 30$ ins.;
$= 75$ "	(173 " "	" $d = 36$ ins.;
$= 70$ "	(162 " "	" $d = 42$ to 60 ins.

Formula recommended by R. D. Wood & Co., Philadelphia:—

$$t = \frac{(p + 100)d}{7200} + 0.333 \left(1 - \frac{d}{100}\right) \dots\dots\dots (3)$$

Here, $s = 3600$ (or $2s = 7200$); p' is assumed at the constant value 100; and the added thickness to allow for rough handling is represented by the last term, a variable dependent on the diameter. But formula (3) easily reduces to

$$t = \frac{(p + 76)d}{7200} + 0.333 \dots\dots\dots (4)$$

which is readily comparable with (2).

Kinds of Pipe Joints.—Cast iron pipe 3 ins. or more in diameter comes in a standard laying length of 12 feet. There are four principal types of joints, namely, (1) bell and spigot; (2) turned, page 1235; (3) flanged, page 1235; and (4) flexible joint, page 1238. These are discussed as follows.

(1) **Bell and Spigot Joint Pipe** (see p. 1220) is the most common, being almost universally employed when cast iron pipe is to be laid in trenches and back-filled. In laying the pipe it is customary to begin with some "special" as a gate or tee, etc., thrusting the spigot end of each pipe into the bell of the piece previously placed, "bell holes" having been dug in the trench where each joint is to come. When blocked or tamped to proper line and grade the joints are caulked at the inner or spigot end with oakum, jute or hemp, and then the balance of the joint is run with hot lead, and caulked tightly. In order to confine the molten lead so it will fill the joint flush with the end of the bell, a gasket is clamped around the entering pipe tightly against the bell of the other, leaving an opening at the top for pouring. Improvised gaskets may be made wholly out of clay, but manufactured gaskets composed of layers of rubber and hemp cloth, and backed by steel springs are universally employed. The ends are clamped nearly together, a pouring hole is made with clay, and the metal poured. (See page 1219 for notes on pipe laying; page 1280 for lead-melting furnace.)

This table (6) may be used in several ways: First, to determine the maximum discharging capacity of any size of pipe under a given head; second, to find the diameter of pipe for a given discharge and given head; third, to ascertain the frictional resistance or loss of pressure for a given rate of discharge; fourth, to find the quantity of water flowing in any pipe, from the radius of pressure.

See examples on following page.

EXAMPLES IN USE OF TABLE 6, PRECEDING.

(1) *The maximum discharging capacity*, for instance, of 8500 ft. of 6" straight cast iron pipe, under a head of 195 ft., may be found as follows: First ascertain the frictional head for 1000 ft., thus: $195 \text{ ft.} \div 8.5 = 22.94$ as the fric. head in ft. per 1000 ft. By referring to the table, 1000 ft. of 6" pipe under 23.01 ft. head will discharge 500 galls. per min.

(2) *To find the diam. of pipe for a given discharge*.—To deliver, say, 4,250,000 galls. per 24 hrs., the dist. being 20,000 ft. and the head 130 ft. The fric. head per 1000 ft. is $130 \div 20 = 6.5$ ft., and the table shows that under 6.19 ft. head per 1000 ft. a 16" pipe will discharge 4,320,000 galls.

(3) *To ascertain the pressure at any point* in a line of water main, given its diam., rate of disch. and static head against which the water is forced. Assume that 500 galls. of water are to be forced per minute, through 5000 ft. of 8" cast iron pipe, laid on an incline to a height of 75 ft.; what would be the varying pressure at each 1000 ft. from the pumps? The table shows a fric. head of 5.64 ft. per 1000 ft. of 8" pipe, discharging 500 galls. per min. If the dist. is 5000 ft., the pressure required to overcome fric. is $5 \times 5.64 = 28.20$ ft. head, and the total resistance head at pumps is $28.2 + 75 \text{ ft.} = 103.2$ ft., and for every 1000 ft. from the pumps, this head is diminished 5.64 ft. + the vert. ascent; that is, at 3000 ft. from the pumps the resistance head is 61.92 ft. Resistance head in ft. $\div 2.3 =$ pres. in lbs. per sq. in.

(4) *The volume of water flowing* in a pipe may be found by ascertaining the loss of pressure or fric. resistance per 1000 ft. of pipe. To this end, if two accurate gages, entirely similar in all respects, and placed 1000 ft. apart on a line of level 12" pipe, show a loss of 0.5 lb., the nearest figures indicate a flow of 600 galls. per min.; if the loss is $2\frac{1}{2}$ lbs., a flow of 1400 galls. per min., etc. Due allowance should be made for diff. in elev. of points of observation.

PIPE-LAYING NOTES.

The following Notes on Pipe-Laying relate to the re-construction of the distributing system at The Dalles, Oregon, in the winter of 1898-9, and are taken from the writer's note book:

1 yarner can yarn 1000 l. f. of 6" to 10" C. I. pipe per day.

2 caulkers can caulk 1000 l. f. of 6" to 10" C. I. pipe per day.

Gang laid 700 l. f. 8" pipe on 4th Street one day = $1\frac{1}{2}$ c. per l. f.

Gang took up 2400 l. f. 8" pipe for \$60.00, at rate of $2\frac{1}{2}$ c. per l. f.

Cost of cutting 4", 6", 8", 10", 12" pipe = 6c, 9c, 12c, 15c, 18c.

Cheaper to place all pipe over 10" with derrick unless ground is sandy and soft; handle 8" and 10" pipe with rope at each end.

4" and 6" pipe can be rolled in trench if soft; otherwise by hand.

4" pipe @ $20\frac{1}{2}$ = 240 lbs.; two men can carry on shoulders.

6" pipe @ $32\frac{1}{2}$ = 384 lbs.; three men can carry with two bars (1 behind.)

8" pipe @ $45\frac{1}{2}$ = 540 lbs.; four men can carry with two bars.

10" pipe @ $65\frac{1}{2}$ = 780 lbs.; six men can carry with three bars.

12" pipe @ $75\frac{1}{2}$ = 900 lbs.; eight men can carry with four bars.

12" pipe @ $85\frac{1}{2}$ = 1020 lbs.; nine men can carry with five bars (1 behind.)

Trucked 15-4" (3600#), 9-6" (3456#), 7-8" (3780#), 4-10" (3120#).

3-12" (2700 to 3060#) pipe per load, two horses, two men to unload.

Required $\frac{1}{2}$ cord wood for melting 1000# lead (for 1000 ft. 8" pipe).

Required $\frac{1}{2}$ cord wood for melting 250 ft. of laid, 8" pipe for taking up.

Bell-holes were dug around the joints and fires kindled.

Weights and Dimensions of Cast Iron Pipe and Specials.—The following tables are mainly from a pamphlet issued by the Engineering Department of the Metropolitan Water Board of Boston. The weight of castings is based on one cubic inch of cast iron weighing 0.2604 lb. These tables are selected because they are based on methods and details quite generally approved not only in New England but elsewhere. Various foundries furnish details differing more or less from these and from each other, and hence the subjoined data of weights, etc., must necessarily be approximate. Five classes of pipe are recognized as standards: Class A for heads up to 115 ft. (50 lbs.); class B for heads up to 150 ft. (65 lbs.); class C for heads up to 200 ft. (87 lbs); class D for heads up to 250 ft. (109 lbs.); and class E for heads up to 300 ft. (130 lbs. per sq. inch). (See formula (2), page 1215.)

* See also Table 34, following.

(2) **Turned and Bored Joint Pipe** (see page 1215) is rarely used in the United States. During extremely cold weather the joints are liable to pull apart. If there is no danger from this cause, this kind of pipe will perhaps be economical if the cost of boring the bell end and turning the spigot end does not exceed the cost of lead joint for the ordinary bell and spigot pipe.

(3) **Flanged Joint Pipe** (see page 682) or simply flange pipe is used for special connections and open work, generally at the ends of pipe lines, as in pump-houses, gate chambers, etc. The pipes come in 12-ft. lengths, and the flanges are bolted together, with rubber or other packing between. The following represents the practice of R. D. Wood & Co., of Philadelphia, adopting the standard of National Ass'n of Master Steam and Hot Water Fitters and the Am. Soc. of Mechanical Engineers, in flange diameters and drilling:

Note.—Flexible Joint Pipe is described on page 1238.

25.—PROPERTIES OF STANDARD FLANGE PIPE. PART I.—PRESSURES 25 AND 50 LBS.

Notes.—5", 7", 9" and 15" are odd sizes, made to order only. 4" to 24" usually in stock, regularly made in 12' lengths, faced 12" short to allow for gasket. Bolts and gaskets furnished only on order. The flanges are finished approximately $1\frac{1}{4}$ times the thickness of pipe + $\frac{1}{8}$ ". Drilling is $\frac{1}{8}$ " larger for $\frac{1}{2}$ " bolts; and $\frac{1}{8}$ " larger for $\frac{3}{4}$ " bolts and above, than corresponding bolt diameters, and all drilling is in fours or multiples thereof.

Pressures given are for water; when pipes are required for steam, the pressure should not exceed $\frac{2}{3}$ of that given in table. Dimensions are in inches; weights in lbs. Weights are approximate only.

(4) **Flexible Joint Pipe** (page 1215) is particularly advantageous and economical when it is necessary to carry the pipe line across a stream of any considerable size. If the stream is navigable and vessels are liable to anchor, the bed of the stream must be dredged on the line of the pipe, and a line of guide piles is often driven for this purpose. These piles also serve later in laying the pipe in the dredged trench. The process of laying the pipe is comparatively simple. Beginning at one shore, connection is made with the line laid up to that point (in a gradually descending deep trench toward the stream). An improvised scow with a run-way or incline is well suited to the purpose. The pipes are laid successively on the run-way, the joints are leaded, and the scow pulled ahead, allowing the pipe to gradually settle to the bottom of the trench without straining the joints excessively.

Fig. 25.

In pouring the lead for any joints the two adjacent pipes must be in a straight line. Sometimes trestle work is employed, in shallow water, and the pipes are lowered into place by block and tackle. The method of assembling the pipe on the bank, and then dragging the whole connected line into the stream is very liable to strain the joints and even pull them apart, as sometimes happens.

Flexible joint pipe is manufactured in pipe length, including pipe and joint, with bell-end machined inside; or the cast knuckle joints with flange ends or bell and spigot ends may be ordered separately for connecting with ordinary pipe.

Flexible joints are used not only with cast iron pipe but with wrought iron and steel pipe as well.*

* For design of flexible joint in connection with 52-in. riveted steel pipe. see Trans. Am. Soc. C. E., Vol. XXXIV, p. 23.

AMERICAN WATER WORKS ASSOCIATION

* STANDARD SPECIFICATIONS
FOR
CAST IRON PIPE AND SPECIAL CASTINGS

WITH TABLES OF DIMENSIONS,
THICKNESSES AND WEIGHTS.

Adopted May 12, 1908.

STANDARD SPECIFICATIONS.

DESCRIPTION OF PIPES.

Section 1. The pipes shall be made with hub and spigot joints, and shall conform accurately to the dimensions given in Tables 26 and 27. They shall be straight and shall be true circles in section, with their inner and outer surfaces concentric, and shall be of the specified dimensions in outside diameter. They shall be at least 12 feet in length, exclusive of socket.

Pipes with thickness and weight intermediate between the classes in Table 27 shall be made of the same outside diameter as the next heavier class. Pipes with thickness and weight less than shown by Table 27 shall be made of the same outside diameter as the Class A pipe; and pipes with thickness and weight more than shown by Table 27 shall be made of the same outside diameter as the Class D pipe.

All pipes having the same outside diameter shall have the same inside diameter at both ends. The inner diameter of the lighter pipes of each standard outside diameter shall be gradually increased for a distance of about 6 inches from each end of the pipe so as to obtain the required standard thickness and weight for each size and class of pipe.

For pipes of each size from 4-inch to 24-inch inclusive, there shall be two standards of outside diameter, and for pipes from 30-inch to 60-inch inclusive, there shall be four standards of outside diameter, as shown by Table 26.

For pipes 4-inch to 12-inch inclusive, one class of special castings shall be furnished, made from Class D pattern. Those having spigot ends shall have outside diameters of spigot ends midway between the two standards of outside diameter as shown by Table 26, and shall be tapered back for a distance of 6 inches.

For pipes from 14-inch to 24-inch inclusive, two classes of special castings shall be furnished; Class B special castings with Classes A and B pipes, and Class D special castings with Classes C and D pipes; the former shall have cast on them the letters "AB" and the latter "CD." For pipes 30-inch to 60-inch inclusive, four classes of special castings shall be furnished, one for each class of pipe, and shall have cast on them the letter of the class to which they belong.

ALLOWABLE VARIATION IN DIAMETER OF PIPES AND SOCKETS.

Section 2. Special care shall be taken to have the sockets of the required size. The sockets and spigots will be tested by circular gages, and no pipe will be received which is defective in joint room from any cause. The diameters of the sockets and the outside diameters of the spigot ends of the pipes shall not vary from the standard dimensions by more than 0.06 of an inch for pipes 16 inches or less in diameter; 0.08 of an inch for 18-inch, 20-inch and 24-inch pipes, 0.10 of an inch for 30-inch, 36-inch and 42-inch pipes; 0.12 of an inch for 48-inch, and 0.15 of an inch for 54-inch and 60-inch pipes.

ALLOWABLE VARIATION IN THICKNESS.

Section 3. For pipes whose standard thickness is less than 1 inch, the thickness of metal in the body of the pipe shall not be more than 0.08 of an inch less than the standard thickness, and for pipes whose standard thickness is 1 inch or more, the variation shall not exceed 0.10 of an inch, except

* Mr. J. M. Diven, Sec'y Am. W. W. Ass'n, writes the author as follows, under date of Sept. 3, 1908: "The specifications are not absolutely perfect yet, nor has there been any agreement between the various associations as to a universal standard. This is something greatly to be desired, and which I trust will be brought about in the next two or three years."

that for spaces not exceeding 8 inches in length in any direction, variations from the standard thickness of 0.02 of an inch in excess of the allowance above given shall be permitted.

For special castings of standard patterns a variation of 50 per cent greater than allowed for straight pipes shall be permitted.

DEFECTIVE SPIGOTS MAY BE CUT.

Section 4. Defective spigot ends on pipes 12 inches or more in diameter may be cut off in a lathe and a half-round wrought-iron band shrunk into a groove cut in the end of the pipe. Not more than 12 per cent of the total number of accepted pipes of each size shall be cut and banded, and no pipe shall be banded which is less than 11 feet in length, exclusive of the socket.

In case the length of pipe differs from 12 feet, the standard weight of the pipe given in Table 27 shall be modified in accordance therewith.

SPECIAL CASTINGS.

Section 5. All special castings shall be made in accordance with the cuts and dimensions given in the tables forming a part of these specifications.

The diameters of the sockets and the external diameters of the spigot ends of the special castings shall not vary from the standard dimensions by more than 0.12 of an inch for castings 16 inches or less in diameter; 0.15 of an inch for 18-inch, 20-inch and 24-inch; 0.20 of an inch for 30-inch, 36-inch and 42-inch, and 0.24 of an inch for 48-inch, 54-inch and 60-inch. These variations apply only to special castings made from standard patterns.

The flanges on all manhole castings and manhole covers shall be faced true and smooth, and drilled to receive bolts of the sizes given in the tables. The manufacturer shall furnish and deliver all bolts for bolting-on the manhole covers, the bolts to be of the sizes shown on plans and made of the best quality of mild steel, with hexagonal heads and nuts and sound well-fitting threads.

MARKING.

Section 6. Every pipe and special casting shall have distinctly cast upon it the initials of the maker's name. When cast especially to order, each pipe larger than 4-inch may also have cast upon it figures showing the year in which it was cast and a number signifying the order in point of time in which it was cast, the figures denoting the year being above and the number below, thus:

1908	1908	1908
1	2	3

etc., also any initials, not exceeding four, which may be required by the purchaser. The letters and figures shall be cast on the outside and shall not be less than 2 inches in length and $\frac{1}{8}$ of an inch in relief for pipes 8 inches in diameter and larger. For smaller sizes of pipes the letters may be 1 inch in length. The weight and the class letter shall be painted conspicuously in white on the inside of each pipe and special casting after the coating has become hard.

ALLOWABLE PERCENTAGE OF VARIATION IN WEIGHT.

Section 7. No pipes shall be accepted the weight of which shall be less than the standard weight by more than 5 per cent for pipes 16 inches or less in diameter, and 4 per cent for pipes more than 16 inches in diameter, and no excess above the standard weight of more than the given percentage for the several sizes shall be paid for. The total weight to be paid for shall not exceed for each size and class of pipe received the sum of the standard weights of the same number of pieces of the given size and class by more than 2 per cent.

No special casting shall be accepted the weight of which shall be less than the standard weight by more than 10 per cent for pipes 12 inches or less in diameter, and 8 per cent for larger sizes except that curves, Y-pieces and breeches pipe may be 12 per cent below the standard weight, and no excess above the standard weight of more than the above percentages for the several sizes will be paid for. These variations apply only to castings made from the standard patterns.

QUALITY OF IRON.

Section 8. All pipes and special castings shall be made of cast iron of good quality, and of such character as shall make the metal of the castings

strong, tough and of even grain, and soft enough to satisfactorily admit of drilling and cutting. The metal shall be made without any admixture of cinder iron or other inferior metal, and shall be remelted in a cupola or air furnace.

The contractor shall have the right to make and break three bars from each heat or run of metal, and the test shall be based upon the average results of the three bars. Should the dimensions of the three bars differ from those given below, a proper allowance therefor shall be made in the results of the tests.

TESTS OF MATERIAL.

*Section 9. Specimen bars of the metal used, each being twenty-six inches long by two inches wide and one inch thick, shall be made without charge as often as the engineer may direct, and in default of definite instructions the contractor shall make and test at least one bar from each heat or run of metal. The bars when placed flatwise upon supports twenty-four inches apart, and loaded in the center, shall support a load of 2,000 pounds, and show a deflection of not less than 0.30 of an inch before breaking; or if preferred, tensile bars shall be made which will show a breaking point of not less than 20,000 pounds per square inch.

CASTING OF PIPE.

Section 10. The straight pipes shall be cast in dry sand molds in a vertical position. Pipes 16 inches or less in diameter shall be cast with the hub end up or down, as specified in the proposals. Pipes 18 inches or more in diameter shall be cast with the hub end down.

The pipes shall not be stripped or taken from the pit while showing color of heat, but shall be left in the flasks for a sufficient length of time to prevent unequal contraction by subsequent exposure.

QUALITY OF CASTINGS.

Section 11. The pipes and special castings shall be smooth, free from scales, lumps, blisters, sand holes and defects of every nature which unfit them for the use for which they are intended. No plugging or filling will be allowed.

CLEANING AND INSPECTION.

Section 12. All pipes and special castings shall be thoroughly cleaned and subjected to a careful hammer inspection. No casting shall be coated unless entirely clean and free from rust, and approved in these respects by the engineer immediately before being dipped.

COATING.

Section 13. Every pipe and special casting shall be coated inside and out with coal-tar pitch varnish. The varnish shall be made from coal tar. To this material sufficient oil shall be added to make a smooth coating, tough and tenacious when cold, and not brittle nor with any tendency to scale off.

Each casting shall be heated to a temperature of 300 degrees Fahrenheit immediately before it is dipped, and shall not possess less than this temperature at the time it is put in the vat. The ovens in which the pipes are heated shall be so arranged that all portions of the pipe shall be heated to an even temperature. Each casting shall remain in the bath at least five minutes.

The varnish shall be heated to a temperature of 300 degrees Fahrenheit (or less if the engineer shall so order), and shall be maintained at this temperature during the time the casting is immersed.

Fresh pitch and oil shall be added when necessary to keep the mixture at the proper consistency and the vat shall be emptied of its contents and refilled with fresh pitch when deemed necessary by the engineer. After being coated the pipe shall be carefully drained of the surplus varnish. Any pipe or special casting that is to be recoated shall first be thoroughly scraped and cleaned.

HYDROSTATIC TEST.

Section 14. When the coating has become hard, the straight pipes shall be subjected to a proof by hydrostatic pressure, and, if required by the engineer, they shall also be subjected to a hammer test under this pressure.

* Pipe may be made under higher metal tests when desired. Stock pipe may be made under metal tests as low as 1,800 pounds.

The pressures to which the different sizes and classes of pipes shall be subjected are as follows:

	20-Inch Diameter and Larger. Pounds per Square Inch.	Less than 20-Inch Diameter. Pounds per Square inch.
Class A Pipe.....	150	300
Class B Pipe.....	200	300
Class C Pipe.....	250	300
Class D Pipe.....	300	300

WEIGHING.

Section 15. The pipes and special castings shall be weighed for payment under the supervision of the engineer after the application of the coal-tar pitch varnish. If desired by the engineer, the pipes and special castings shall be weighed after the delivery, and the weights so ascertained shall be used in the final settlement, provided such weighing is done by a legalized weighmaster. Bids shall be submitted and a final settlement made upon the basis of a ton of 2,000 pounds.

CONTRACTOR TO FURNISH MEN AND MATERIALS.

Section 16. The contractor shall provide all tools, testing machines, materials and men necessary for the required testing, inspection and weighing at the foundry, of the pipe and special castings; and should the purchaser have no inspector at the works, the contractor shall, if required by the engineer, furnish a sworn statement that all of the tests have been made as specified, this statement to contain the results of the tests upon the test bars.

POWER OF ENGINEER TO INSPECT.

Section 17. The engineer shall be at liberty at all times to inspect the material at the foundry, and the molding, casting and coating of the pipes and special castings. The forms, sizes, uniformity and condition of all pipes and other castings herein referred to shall be subject to his inspection and approval, and he may reject, without proving, any pipe or other casting which is not in conformity with the specifications or drawings.

INSPECTOR TO REPORT.

Section 18. The inspector at the foundry shall report daily to the foundry office all pipes and special castings rejected, with the causes for rejection.

CASTINGS TO BE DELIVERED SOUND AND PERFECT.

Section 19. All the pipes and other castings must be delivered in all respects sound and conformable to these specifications. The inspection shall not relieve the contractor of any of his obligations in this respect, and any defective pipes or other castings which may have passed the engineer at the works or elsewhere shall be at all times liable to rejection when discovered, until the final completion and adjustment of the contract; provided, however, that the contractor shall not be held liable for pipes or special castings found to be cracked after they have been accepted at the agreed point of delivery. Care shall be taken in handling the pipes not to injure the coating, and no pipes or other material of any kind shall be placed in the pipes during transportation or at any time after they have received the coating.

DEFINITION OF THE WORD "ENGINEER."

Section 20. Wherever the word "engineer" is used herein it shall be understood to refer to the engineer or inspector acting for the purchaser and to his properly authorized agents, limited by the particular duties intrusted to them.

The above weights are per length to lay 12 feet, including standard sockets; proportionate allowance to be made for any variation.

For High Pressure Pipe from 6 inches to 24 inches inclusive, one class of special castings shall be furnished for Classes E and F pipe and one class of special castings for Classes G and H pipe. For 30-inch and 36-inch pipe, one class of special castings shall be furnished for each class of pipe.

30.—LUGS.

Number and Weights of Lugs on Outlets of Different Sizes.
(A. W. W. A).

4 Lugs, 12-14 inches
8 Lugs, 42-60 inches

Fig. 30a.

6 Lugs, 16-26 inches

Fig. 30b.

Nominal Diameter Outlet, Inches.	Number of Pairs of Lugs.	Approximate Weight Lugs on One Bell, Pounds.	Nominal Diameter Outlet, Inches.	Number of Pairs of Lugs.	Approximate Weight Lugs on One Bell, Pounds.

18	6	56	48	8	114
20	6	56	54	8	134
24	6	56	60	8	137

Two pairs of lugs are placed on the vertical axis of each bell, the others at equal distances around circumference. H = depth of bell on all sizes.
 $G = 2.50$ inches, $X = 1.25$ inches, $Y = 1.63$ inches, for 12 to 24 inches inclusive.
 $G = 3.00$ inches, $X = 1.50$ inches, $Y = 2.00$ inches, for 30 to 60 inches inclusive.

31, 32.—PROPERTIES OF CURVES, BELL AND SPIGOT, $\frac{1}{4}$, $\frac{1}{2}$, $\frac{3}{4}$.

III.d.—WROUGHT IRON PIPE.

Wrought Iron Pipe corrodes more rapidly than cast iron, and less rapidly than steel. Its first cost, in the smaller sizes, is less than the former; and in all sizes it is greater than the latter. Between cast iron on the one hand and the steel on the other the use of wrought iron in pressure pipe lines has become limited, but it yet finds a demand in the smaller sizes of pipe for distributing systems. It remains to be seen whether the few remaining manufacturers of wrought iron pipe will be able to offer convincing proofs of the superior merit and ultimate economy of their article, as claimed. More attention is paid now to suitable coating for pipes than formerly, and a steel pipe well coated when laid should last from 25 to 40 years in ordinary soil, and if occasionally cleaned and painted it will last much longer. Wrought iron pipe may be manufactured in the same forms as steel pipe (III.e), but it is usually lap-welded, seldom riveted.

III.e.—STEEL PIPE.

Steel Pipe is usually designated by the kind of "seam" or "joint." The latter term is generally used with reference to the (end) connection between two pipes, and frequently also to the longitudinal seam at the joining of plates in the pipe itself. Seams or joints in a pipe may be lap-welded, spiral riveted, longitudinal riveted, or locking-bar. Riveted (longitudinal) joints may be lap- or butt-, and be (single-), double- or triple-riveted, with (single or) double straps. Single riveting or single straps are seldom used for longitudinal joints. The end joints for pipes may be screw-, bell-and-spigot- (rarely used), flange- (welded, riveted, or screw), single-riveted-, patent-locking-, etc. A few of these will be described as follows:

Riveted Steel Pipe is especially economical for large diameters, subjected to pressure head of 300 ft. or more. For heads between 200 and 300 ft. riveted steel has to compete with cast iron pipe; and for heads under 200 ft. both riveted steel and cast iron pipe have to compete with wood stave pipe, especially in the West where lumber is plentiful.

The thickness of steel plates is proportioned by the formula—

$$t = \frac{(p + p')d}{2se} + c \dots \dots \dots (1)$$

where t = thickness of steel shell, in inches;

d = inside diameter of pipe, in inches;

h = pressure head in ft. (= 2.304 p);

p = pressure of water in lbs. per square inch (= 0.434 h);

p' = allowance for water ram, in lbs. per square inch;

s = allowable tensile stress of steel, in lbs. per square inch;

e = efficiency of riveted joint, say 0.50 to 0.80;

c = thickness to be added to plate for corrosion, etc.

Based on a safety factor of 4, s is assumed at 15,000 (to 16,000) lbs; and c may be assumed at say $\frac{1}{16}$ in.

The practical working formula will result as follows, assuming p' at 80 lbs. (see page 1215):

$$t = \frac{(p + p')d}{30000e} + \frac{1}{16} = \frac{(0.434h + 80)d}{30000e} + 0.0625 \dots \dots \dots (2)$$

If h = the static head in feet, we have, from (2),

$$h = \frac{69120e}{d} (t - \frac{1}{16}) - 184.32 \dots \dots \dots (3)$$

In designing the riveting of longitudinal seams, we have, if F = total tension per lin. inch of seam, due to p and p' ,

$$F = \frac{d}{2} (p + p') = d(0.217h + 40) = 1500 (t - c) \dots \dots \dots (4)$$

in which F should not exceed the bearing- nor the shearing resistance of the rivets. The bearing value may be assumed at 16,000 lbs. per square inch on the thickness of plate $t - c$, as it is assumed that c is the allowance for corrosion; while the shearing value may be assumed at say 10,000 lbs. per square inch of rivet section. The diameter of rivet is approximately twice the thickness of the plate.

The following is a table of pitches and dimensions of rivets adopted in the manufacture of the 42-in. pipe for the Seattle (Wash.) Water-works, constructed in 1900:

Thickness of Steel, in inches.....	$\frac{1}{8}$	$\frac{1}{4}$	$\frac{1}{8}$	$\frac{3}{8}$	$\frac{1}{2}$
Diameter of rivets, in inches.....	$\frac{3}{8}$	$\frac{1}{2}$	$\frac{5}{8}$	$\frac{3}{4}$	$\frac{7}{8}$
Diameter of rivet holes, in inches.....	$\frac{1}{8}$	$\frac{5}{8}$	$\frac{1}{2}$	$\frac{1}{2}$	$\frac{3}{4}$
Pitch in double riveted seams, in ins ..	1.75	2.00	2.25	2.50	2.50
Pitch in single riveted seams, in ins ..	1.40	1.60	2.00	2.25	2.25
Distance between rows on double riveted seams, in inches.....	1.50	1.75	2.00	2.00	2.00
Lap from center of rivet to edge of plate, in inches.....	.750	.875	1.00	1.00	1.125

The edges of all plates are bevel sheared for caulking. Shop-riveting and caulking are invariably done by machine. For thick plates the rivets may be countersunk on inside of pipe. The field-riveting and caulking are usually done by hand, but machine riveters and caulkers are sometimes employed, not always to advantage. The field work consists in joining the pipes together in the trench and making them water-tight under pressure. If the end joints are lap-riveted there must necessarily be alternate courses with two separate diameters, but the internal diameters of the smaller course shall be "the diameter" of the pipe. The internal diameter of the larger course must equal exactly the external diameter of the smaller course. Pipes of ordinarily large diameter usually leave the shop made up in four courses, and in length from 20 to 30 ft., after being tested to a sufficient hydrostatic pressure, and suitably coated (see page 358, etc.).

In shipment it is well to bear in mind that a "full" carload cannot always be made up with pipes of the same diameter if large.

When laid in the trench the longitudinal seams should be at the top of the pipe, staggered not less than 6 inches.

* **Locking-Bar Joint Pipe** is designed to supplant the riveted joint.

Fig. 46 shows a transverse section of the (longitudinal) bar and joint and also the (end) joint ring. In manufacture, the edges of the plate are upset and inserted in the grooves on either side of the locking bar. The bar is then subjected to a great hydraulic pressure, tightly locking the plates in a highly efficient manner. No riveted longitudinal joints are used. Sleeves or joint rings are used for end joint connections of pipes and are run with lead; or the end joints may be riveted.

Fig. 46.

Lap-Welded Pipe is seldom used in the pressure pipe line; it is better adapted to use in the distributing system (see page 1280). The four principal types used are those with screw ends or flange ends (Section 36), Converse Joint (p. 1283), and Matheson Joint (p. 1281).

Spiral Riveted Pipe (p. 680) is used largely in hydraulic mining.

III.—PRESSURE PIPE ATTACHMENTS.

Brief mention will be made of some of the more important items in connection with an ordinary pressure-pipe line. The varying conditions are so great in different lines that the merest hints only will be given.

* This form of joint was brought prominently to the attention of American engineers in 1898 by an article published in Eng. News, Vol. XXXIX, p. 373, describing its use in connection with the construction of a large pipe line in Australia.

Fig. 47 shows a **Sluice-Gate** for the inlet end of the pipe at the head-works, and Fig. 48 shows **Stand and Wheel** for operating same. Each may be fastened to either masonry (by stone-bolts) or to timber (by screw-bolts). This pattern is suitable for large inlets, 30 ins. or more in diameter. The gear-wheel is often horizontal instead of vertical.

Fig. 47.—Sluice-Gate for Headworks.

Fig. 48.—Stand and Wheel for Operating Sluice-Gate.

Air Relief Valves, or "**Air Valves**," are placed at summits of pipe lines to afford relief from air pressure or from vacuum. As the pipe fills with water the valve operates so as to allow the air to escape, but closes against the outlet of the water. As the water in the pipe subsides, the valve allows the air to enter the pipe and prevent collapse from vacuum. If air is allowed

Fig. 49.

Fig. 50.

to collect at summits without air valves it is clearly seen that the water area of the pipe at those points, and hence the flow, will be decreased accordingly; and also that the pipe is more liable to leak and burst (from air-

from water pressure). Air valves may be single, or they may be aged in clusters to operate consecutively. There is an advantage in ing a stop-valve between the air valve and the top of the main pipe, so water can be shut off during repairs. Valves should be protected by 1- or metal casings and be out of reach of the frost.

Fig. 49 illustrates the Ludlow automatic lever and float air valve, and 50 the globe air valve.

Fig. 51 shows section and plan of Metropolitan Water Works air valve, table of dimensions.

Fig. 51.

46.—M. W. W. AIR VALVES. (FIG. 51.)

Dimensions are in inches; weights, in pounds.

Standpipes (small) are sometimes erected at the summits of pipe lines serve both as air valves, and also as piezometers for determining the hydraulic grade line (see p. 1159). They are often preferred to air valves where the static head is not great.

Gate Valves, stop valves, gates, or valves, as they are variously termed of numerous designs, suited to special purposes. The best manufacturers are beginning to standardize their product so that there is very little difference in quality of material and service. But there is a vast difference in length of service between these standard makes and most of the cheaper valves thrown upon the market. Waterworks engineers, generally, fully realize the importance of securing at all times the best article even at the water first cost. It is economy in the end. The best gates are bronze-wounded.

Fig. 55, page 1285, shows a section of the Chapman valve with wedge shaped gate. Fig. 52, below, shows a section of a double gate valve of the Ludlow type; and Fig. 53, views of the gates and wedges. The pipe con-

Fig. 52.—Ludlow Bronze Mounted Double Gate Valve With Bolted Stuffing Box.

Fig. 53.—Style of Gates and Wedges for Double Gate Valves.

ns may be bell- (as shown in the illustrations), flange- or screw-, as ed. Gates are designed for either vertical or horizontal (the larger position, and for operating by hand or "power," with screw, piston, or gearing (gates under 16 ins. in size are seldom geared). They are manufactured with or without by-pass relief. The by-pass is useful in long pipe lines without impact, and in equalizing the pressure on both of a gate when being opened or closed.

Using gears. With wrench on main stem, 67 $\frac{1}{2}$ turns will open the ch, and 76 $\frac{1}{2}$ turns the 24-inch valve.

Commonwealth of Massachusetts
Metropolitan Water Works.

Vertical Gate Valves
with & without Gears

Sectional Elevation
s for 20" & 24" valves.

Note.—The table above and the accompanying sketches exhibit the principal dimensions and data of the M. W. W. valves. All wrench nuts are 1 $\frac{1}{4}$ " square by 2" deep. Turn wrench toward right hand to open valves, except on nut on main stem of a 20-inch or a 24-inch valve. 20-inch and 36-inch valves have 6-inch by-passes. The valves of these by-passes (if Chapman) require 21 turns to open. Others have a pair of lugs on each extremity of the horizontal diameter of each bell, except the 30-inch valve, in which case the pair of lugs next to the dome is omitted for lack of room. The remaining pairs of lugs on the 20, 24 and 30-inch valves are spaced equally around the circumference of the bell. The total weights were obtained by weighing some of the valves. The weights of the component parts were computed from the neat dimensions of the drawings; the rough castings will weigh 25% to 33% more.

Blow-Offs are placed on the bottom of pipes at depressions in the pipe line for cleaning out or emptying the conduit. They consist essentially of a small pipe, say from 4 to 16 inches in diameter, leading to some suitable point where the waste can be discharged. A gate is inserted near the main pipe line. See Tables 16, 17, 38 and 39, and preceding.

IIIg.—“SPECIALS.”

“Specials” are usually of cast iron and include bends, reducers, tees, wyes, and in fact many other shapes that enter also into the distributing system (see preceding and following tables). Fig. 56 shows the method of connecting wood-stave pipe with a cast special. The socket or bell of the casting is usually about 6 inches deep, with offset equal to thickness of staves. Fig. 57 is a front half view of special casting for connecting a small

Fig. 56.

Fig. 57.

Fig. 58.

Fig. 59.

branch or a blow-off with a wood-stave pipe. Note the attached lugs (bosses) or shoes *s* for holding the ends of the steel bands which cinch around the opposite side of the pipe. These shoes are shown in side view by Fig. 58, and in the end view by Fig. 59, the band passing between the prongs.

E.—DISTRIBUTING SYSTEM.

Cast Iron Pipe is by far the best that can be used, although the first cost is greater than that of lap-welded pipe. For sizes, details and weights of cast iron pipe, see tables under IIIc, page 1214 and following.

It is to be noted especially that there should be no “dead ends” in a distributing system, i. e., cross connection should be made at terminal points, as at ends of streets.

Fig. 60 is a Portable Lead-Melting Furnace and ladle for pouring the joints. (See page 1215 for description and use of gasket.)

Matheson Patent Lock Joint Pipe (steel lap-welded) is manufactured in lengths up to about 20 feet (average about 17 to 18 feet over all, according to size) and is tested to 500 lbs. hydraulic pressure per square inch.

Tables 50-54, on following page, give sizes and weights of pipe and specials; also, lead required per joint.

(Cast Hub.)

For details of specials see National Tube Works catalog.

Pipe-Dipping Tank.—The writer has found it convenient in some cases to order the lap-welded pipe from the manufacturer uncoated, and to coat it in the field before laying. For this purpose a dipping tank is used as shown in Fig. 63. The tank should be about 20 ft. long, 2 ft. wide and 2 feet deep. Such a tank constructed of No. 12 gauge steel will weight about 700 lbs. It is set over an improvised brick furnace, cheaply constructed and provided with a smoke stack. Hard and liquid asphaltum are mixed in it in

Fig. 63.—Pipe-Dipping Tank.

the proper proportion and the pipe is dipped when it has reached the proper temperature. Approximately, the number of pounds of asphalt required per hundred feet of pipe is equal to $5.5 \times$ diameter of pipe in inches.

Tapping Machines are employed for tapping mains for service connections. There are many styles, more or less expensive. The Mueller tap-

Fig. 64.—Mueller Tapping Machine.

ing machine is illustrated in Fig. 64. For water mains, the machine complete includes:

- 1 each, Combined Drill and Tap— $\frac{1}{2}$, $\frac{3}{8}$, $\frac{1}{4}$ and 1 inch.
- 1 each, Screw or Hexagon, Plug— $\frac{1}{2}$, $\frac{3}{8}$, $\frac{1}{4}$ and 1 inch.
- 4 Malleable Iron Saddles; any size.
- 1 Chain for any size of Pipe.

Black or Galvanized Pipe of "standard" weight as manufactured by the National Tube Co. is shown in the following Table. For the "extra strong" pipe the 1-in. size is 0.182 in. thick, and 12-in. size 0.500 in.; while the "double extra" is 0.364 in. and 0.875 in. thick, respectively.

Ex.—What is the capacity of a pipe 1 1/4 in. dia., and 150 ft. long, the head being 50 ft.? Solution.— $H = \frac{50}{150}L = .333L$; hence, for a 1 1/4 in. pipe the discharge is 35.6 gallons per min.

Gate Valves should be of the best quality.

Fig. 65 shows a section of standard bronze mounted babbitt seat valve, up to 15 ins., as manufactured by the Chapman Valve Co. of Indian Orchard, Mass.

Fig. 66 shows a section of the Eddy gate valve.

Hydrants are connected with transverse pipes leading from the street mains, and hence it will be seen that there is considerable hydrostatic pressure acting horizontally against them at the bottom. This should be resisted by a strong stone backing when the hydrant is set.

EXCERPTS AND REFERENCES.

The New Water-Works Reservoir at Trenton, N. J. (By C. A. Hague. Eng. News, June 13, 1901).—Six illustrations: Section of reservoir, cross-section of wall and embankment; view of gate house; plans and sections of outlet pipe.

Iron or Wooden Lock Gates; Cost of Construction and Maintenance (Eng. News, Oct. 9, 1902).

A Stress Diagram for Water-Tank Hoops (By Ballinger & Perrot. Eng. News, Mar. 5, 1903).

Four Systems of Softening Water for Industrial Purposes (Eng. News, July 2, 1903).—Described and illustrated.

A Proposed High-Pressure Water-Supply System for Fire Protection in Chicago (Eng. News, Mar. 3, 1904).—Illustrations: Main conduit; details of steel and cast-iron pipe; details of fire-boat connection; section of main conduit lateral; maps of high-pressure water supply systems for fire protection in different cities.

Experience in Thawing Water Pipes By Electricity (Eng. News, Mar. 17, 1904).

The Five Dams and Wood-Stave Conduit of the Southern California Mountain Water Co. (Eng. News, April 7, 1904).—Fifteen illustrations; and 13 tables, including cost data.

The Philadelphia Filtration System (Eng. News, Dec. 8, 1904).—Numerous illustrations.

Cost of Laying a 12-in. Water Pipe Across a River (Eng. News, Mar. 2, 1905).—The labor cost of building 44 A-frames, placing and caulking the 516-ft. pipe line, was \$122.

A Diagram for Estimating the Yardage of a Trench (Eng. News, July 6, 1905).—Quantities in cu. yds. for various widths in ft., up to 20 ft., and various depths in ft., up to 30 ft.

Purification of Water by Copper Sulphate (By D. D. Jackson. Eng. News, Sept. 21, 1905).—For other papers and discussions, see Eng. News of Nov. 30, 1905.

The Baiseleys, Springfield, Forest Stream, and Hempstead, Filter Plants, Borough of Brooklyn, New York (Eng. News, Aug. 23, 1906).—Table showing the net amount of water filtered at two mechanical and at two slow sand filter plants, during the year 1905; following totals are reproduced:

Baiseleys (mechanical).....	1,435.5	million gals.	@	\$6 53	p. m. g.
Springfield (mechanical).....	694.6	"	"	9.58	"
Hempstead (slow sand).....	416.8	"	"	2.89	"
Forest Stream (slow sand).....	1,075.3	"	"	2.28	"

The Cost of Clearing and Grubbing a Reservoir Site (By J. Griggs. Paper, A. S. of Mun. Imp., Oct., 1906; Eng. News, Nov. 29, 1906).

Disjointing Cast-Iron Water Mains (Eng. News, Oct. 10, 1907).—Methods used.

Repairing a Remarkable Leak in a Reservoir Embankment at Providence, R. I. (Eng. News, Oct. 17, 1907).—Described and illustrated.

Diagrams for Computing Thickness of Steel Pipe Shells for Different Joint Efficiencies (By R. Muller. Eng. News, April 2, 1908).—The diagrams are based on the following assumptions: Tensile strength of plate, 50 000 lbs per sq. in. of section; factor of safety, 4. Percentage of efficiency of riveted joints, assumed at: single riveted joint, 56%; double-riveted joint, 69%; triple riveted-joint, 75%; double-weld butt joint, 87%; quadruple-riveted joint, 95%.

Method and Cost of Hauling a Water Main Across Channel at Vancouver, B. C. (Eng. News, May 14, 1909).—Illustrated: method, and section through flexible-joint.

Data on Siting Up of Reservoirs (By R. H. Bolster. Eng. News, July 30, 1908).

Repairs to a 72-in. Reinforced-Concrete Jacketed Steel Conduit Under 30-Ft. of Water (By A. W. Cuddeback. Paper, A. W. W. Assn., May, 1908; Eng. News, Aug. 6, 1908).—Illustrated.

The Design of Elevated Tanks and Stand-Pipes (By C. W. Birch-Nord. Trans. A. S. C. E., Vol. LXIV., Sept., 1909).—Specifications.

Water-Works Valuation (By Leonard Metcalf. Trans. A. S. C. E., Vol. LXIV., Sept., 1909).—Numerous bond-, compound-interest-, and sinking-fund formulas, a bibliography of water-works valuation; various kinds of "values" discussed.

Cost of Clearing Water in Settling Basins (By S. Bent Russell. Paper, Central States W. W. Assn., Columbus, O., Sept. 28, 1909. Eng. News, Oct. 14, 1909).—Tables of cost of reservoirs and settling water.

The Purification of the Water Supply of Steelton, Pa. (By J. H. Fuentes. Trans. A. S. C. E., Vol. LXVI., Mar., 1910).—Cost data; illustrations; discussions.

The Use of Sulphate of Alumina and Hypochlorite of Lime in the Storage and Distributing Reservoir of the Nashville Water-Works (By George Reyer. Eng. News, Apr. 7, 1910).—The cost of sulphate of alumina (the ordinary is used) is \$1.07½ per 100 lbs. and of the hypochlorite of lime (it contains about 36% of chlorine) is \$1.50 per 100 lbs. The cost per 1,000,000 gals. of water treated is about \$1.75 for sulphate of alumina and \$1.05 for cost of hypochlorite of lime, making the combined cost of chemicals \$2.80. The water consumption for the year 1909 averaged about 14,000,000 gals., or some 107 gals. per capita.

This article is followed by five others, namely: **A 20,000,000-Gal. Hypochlorite Water-Disinfecting Plant at Minneapolis, Minn.** (By J. A. Jensen). **The Use of Hypochlorite of Lime to Disinfect the Water-Supply of Montreal, P. Q.** (Geo. Janin, C. E.). **The Use of Hypochlorite of Lime in Connection with the Mechanical-Filtration Plant of Harrisburg, Pa.** (G. C. Kennedy, Supt.). **Hypochlorite of Lime as an Adjunct to Mechanical Water Filtration at Quincy, Ill.** (By W. R. Gelston. Paper, Ill. Water Supply Assn., Mar. 8, 9, 1910).—Experiments with Hypochlorite of Lime as a Water Disinfectant at Hartford, Conn. (By Ermon M. Peck, Engr.).

The Groined Arch in Filter and Covered Reservoir Construction (By Thomas H. Wiggin. Paper, Nat'l Assn. Cement Users, Feb. 21-26, 1910; Eng. News, April 7, 1910).—Discussions of: Volumes of elliptical groined arch units; Methods of design; Computation of groined arch as cantilever; Effect of steel in groin arch; Shrinkage and temperature changes; Aid given by earth covering; Construction stresses; Floors of filters and reservoirs; Side walls and division walls; Comparison of groined arch roof with reinforced-concrete slab and beam construction. Illustrations. Table containing data on groined arch roofs for filters and reservoirs.

The Improved Water and Sewerage Works of Columbus, O. (By J. H. Gregory. Trans. A. S. C. E., Vol. LXVII., June, 1910).—Illustrations: Scioto river storage dam; pumping station; offices and laboratories; settling basins; details of filter gallery; details of filters; details of filtered-water reservoirs, etc.

Determination of the Resultant Angle in Laying Out Combined Bonds for Pipe Lines (By C. A. Jackson. Eng. News, Aug. 11, 1910).—Graphical and analytical methods. Example given.

Concrete Tower Enclosing a Water-Works Tank at Gary, Ind. (Eng. News, Oct. 20, 1910).—Tower is octagonal in plan, 34 ft. diam., inside the faces, and 133 ft. high from the grade line. Fully described and illustrated.

Steel Pipes for Water-Works (By Emil Kuichling. Paper, Jour. Am. W. W. Assn., presented Sept. 21-23, 1910; Eng. News, Oct. 27, 1910).—Discussion of wrought-iron and of steel water mains and protective coatings, strength of pipes, vacuum relief valves, capacity of pipe. **Cost of steel and cast-iron pipe.**—"The fact that lock-bar and welded pipe can develop the full strength of the plate, while a riveted seam has only about 70% efficiency, influences the comparative costs. This difference is likely to be made up by a countervailing difference in unit-prices, however. Empirical formulas for cost of steel and cast-iron pipe have been devised by the author (Mr. Kuichling) as below. They assume (1) a water-pressure of 100 lbs., (2) an equivalent pressure, used in design, 50% greater than the static pressure to allow for water hammer and (3) an addendum of ¼" thickness for cast-iron pipe and 1-16" for steel pipe. Taking d as the nominal dia. of pipe, in ins., the cost in cents per lin. ft. is: Cost of steel pipe, $0.4125d^2$; cost of cast-iron pipe, $19+d$ ($0.4845d-0.851$). Subtracting the latter from the former gives the saving due to using steel: Steel pipe cheaper by $19+d$ ($0.072d-$

0.851), which in case of a 36-in. pipe, for example, amounts to 81.7 cts. per ft. For a complete comparison, however, the shorter life of the steel pipe must be taken into account."

Depreciation in Water-Works Operation and Accounting (By Leonard Metcalf. Paper read before the N. E. W. W. Assn., Sept. 22, 1910; Eng. News, Nov. 3, 1910).—Contains sinking-fund and depreciation diagrams and tables.

Pneumatic Caulking of Mains with Lead Wool (By C. C. Simpson, Jr. Paper read before the Am. Gas Institute; Eng. Rec., Nov. 12, 1910).—The Cons. Gas Co. of New York, in an effort to reduce the cost of caulking mains by hand, carried on extensive tests with pneumatic tools and lead wool, and the results were so satisfactory that the pneumatic method was finally adopted on a considerable portion of its work, which includes lines of 48, 36 and 30-in. mains. The article gives detailed costs.

Forms for Concrete (By J. D. Stevenson. Paper before Eng'rs Soc. of Western Penn., Sept. 20, 1910; Eng. Rec., Dec. 10, 1910).—Discussion of experience of three years in construction of the Pittsburgh filtration works (placing about 334,000 cu. yds. of concrete) under the following heads:—Material, design of forms, support of forms, buoyancy of forms, joints, care while filling, and removing forms. For labor costs on forms, see Eng. Rec. of Dec. 17, 1910.

Waterproofing the New Ulm (Minn.) Reservoir (By H. F. Blomquist. Eng. Rec., Dec. 17, 1910).—Reservoir is 75 ft. in diam., 30 ft. deep, capacity 1,000,000 gals., built of reinforced concrete, with a conical reinforced concrete roof. Hard clay, well drained naturally, upon which a 12-in. layer of stone having the voids filled with a wet fine-grained concrete formed the foundation for the 10-in. floor slab proper, which was reinforced near the surface with 16-gauge, 3-in. mesh expanded metal. To insure water tightness, special care was taken during construction to grade the concrete aggregate. Pebbles varying in size from $\frac{1}{4}$ to $2\frac{1}{2}$ in., screened from a gravel bank, were used in the upper floor and walls, as experiments had shown that these pebbles made a denser concrete than broken stone. To reduce the permeability of the concrete to a minimum 20 lbs. of hydrated lime was used to every barrel of cement, and after the forms were removed the walls were brushed and cleaned with steel brushes, and two coats of 1 : 2 cement plastering about $\frac{1}{4}$ in. thick were applied. The mortar for the plastering contained the waterproofing compound to the extent of 10% of the cement used. A slush coat of 1 : 2 cement mortar was floated over the surface of the concrete floor at the time it was laid and a brush coat of cement grout applied to the slushed surface after it had set. After water was let in, some leakage took place and cracks developed. The reservoir then received further treatment, and was rendered watertight.

Illustrations of Important Works:—

Description.

Intake caisson for Cincinnati Water works, showing break
Intake tunnel of Cleveland water works, showing accident
Water tank at Fairhaven, Mass., showing failure
An 8" gate valve for River Rouge, Michigan
Concrete-lined reservoir with concave slopes, Aurora, Ill.

65.—SANITATION.

The Disposal of Refuse from buildings in cities and towns may be classified as follows:

Dry Refuse	{	Paper. {	In large cities, waste paper is collected and sold to paper mills.
		Ashes. {	Ashes are collected and used in extensive filling operations.
Garbage	{	Dumped {	In, fill. Very objectionable—not sanitary. At sea. Expensive; not always sanitary.
		Crematory plants.	Sometimes self-supporting by reason of the residues of oil and grease.
Sewage (House-drainage)	{	Cesspools.	Economical for isolated buildings, as factories, and for suburban districts.
		Sewers	Farm irrigation; largely employed in France. Septic tanks; for inland towns. Chemical process—sludge. Rivers. Raw sewage emptying into streams is becoming prohibitive. Ocean. Boston sewage reaches Moon Island by submarine tunnel where it is pumped into the Bay.

Storm water also becomes sewage when mixed with the latter.

House Drainage is effected by—

Waste Pipes {	Which receive and convey the waste water from baths, basins, sinks, wash tubs, etc., but no human excreta.
Soil Pipes {	Which receive and convey the human excreta, faeces (solid matter) and urine, from closets and urinals; also, general waste.

Drain pipes connect with the waste- and soil pipes at the building line, and convey the waste and soil to the cesspool or sewer.

Generally speaking, the waste- and soil pipes are, in the main, *vertical*, extending from top to bottom *inside* of the building, and connected by branch pipes with the various discharge fixtures; while the drain pipes are

Fig. 1.

Fig. 2.

Fig. 3.

practically *horizontal* and *outside* of the building. Soil- and waste pipes should be extended vertically up through the roof of the building as shown in Fig. 1, to provide for the escape of sewer gas. In order to prevent the latter from finding its way into the rooms, a *trap* is placed on each

pipe leading from the fixture to the soil- or waste pipe. These traps are designated by various letters of the alphabet, but the S-trap (Fig. 2) is perhaps the most common. Their efficiency is reduced when the water evaporates or becomes siphoned out of the trap. Fig. 3 shows a section of Waring's check valve, which remains efficient unless foreign matter lodges between the valve and its seat, or the bearings become too much worn.

Cesspools are excusable in sandy or gravelly soil in new additions to townsites where the water supply is not derived from wells in the immediate locality; or for isolated buildings where cost of sewer would be excessive. A notable example of the latter is the cesspool recently constructed for the discharge of soil and waste from the new boathouse pavilion in Prospect Park, Brooklyn. It is a large cylindrical well with a sand bottom and with sides lined with concrete.

Sewers.—Figs. 4 to 8, in Tables 4 to 8, illustrate five standard sections of sewers, namely, Circular, Catenary, Basket-Handle, Gothic, and Egg or Egg-shape. The proportional dimensions are based on the diametrical height of unity, in each case.

For the Circular section, Fig. 4, there are annexed diagrams of relative area a , velocity v , and discharge q , for relative depths of flow. Thus, if the conduit or sewer is full, a , v and q are assumed to be unity; if the depth is 0.8, $a=0.86$, $v=1.14$, $q=0.98$; if half full, $a=0.5$, $v=1.0$, $q=0.5$, etc. Note that v and q are based on the velocity v being proportional to $\sqrt{r}$, in which r =hydraulic radius in feet (see *Hydraulics*, page 1161). Similar diagrams of area, velocity and discharge may be drawn for the other sections—Catenary (Fig. 5), Basket-Handle (Fig. 6), Gothic (Fig. 7), and Egg (Fig. 8). The Circle, and the Horseshoe with invert, are the most common forms for tunnel construction.

The Egg-shape (Fig. 8) possesses the merit of maintaining a comparatively high value of r (and hence v) for small depths of flow; and it is to be noted that when flowing $\frac{3}{4}$ full depth, r (and v) are greater than when flowing full. (See Table 8.)

Table 1, following, gives the value of r , $\sqrt{r}$ and $a\sqrt{r}$ for Circular sections, advancing by inches up to 20 ft. 11 ins. dia. These properties are useful in designing, i. e., in connection with the use of Kutter's formula, being independent of the grade or slope s .

Table 2, used in connection with Table 1, enables us to find the values of r , $\sqrt{r}$ and $a\sqrt{r}$ for the Catenary, Basket-Handle, Gothic and Egg sections.

Table 3 gives the velocities in Circular brick sewers, unclean, using value of roughness $n=0.015$.

Tables 4, 5, 6, 7 and 8 show properties of Circular, Catenary, Basket-Handle, Gothic, and Egg sections respectively, with relative diameters, both vert. and hor., for equivalent areas. These tables will be found useful for comparison of the different sections in designing.

Table 9 gives the velocities in Egg-shaped sewers which have become somewhat fouled, using value of roughness $n=0.015$.

Size and Grade of Sewers.—The design of sewers may be by either of three methods, namely, (1) by formulas; (2) by tables; (3) by diagrams. For discussion of formulas, see *Hydraulics*, page 1167. In using Kutter's formula the value of c may be determined from $n=0.013^*$ for ordinary brick sewers, and $n=0.015$ for large sewers with unclean surfaces. As there is more or less sand or scouring matter, the velocity of flow should generally be not greater than 5 or 6 ft. per sec.

*For ordinary brick sewers, new and well laid; but it is safer to use $n=0.014$. See, also, pages 1168 and 1188.

VALUES OF r , $\sqrt{r}$ AND $a\sqrt{r}$ FOR *CIRCULAR- CONDUITS OR SEWERS.

Formulas:

hydraulic radius $r = \text{diam. in ft.} \div 4$.velocity v (in ft. per sec.) =

$$v = \frac{c\sqrt{rs}}{4.49} = \frac{c\sqrt{r}}{4.49} \sqrt{s} \quad \left[\text{Values of } \begin{cases} (1) r & \text{in Feet.} \\ (2) \sqrt{r} & \text{in Feet.} \\ (3) a\sqrt{r} & \text{in Feet.} \end{cases} \right]$$

discharge q (in cu. ft. per sec.) =

$$q = a v = c a \sqrt{r} \sqrt{s}$$

Decimals of a Foot.

	" " "	$a\sqrt{r}$	$a\sqrt{r}$ " "	0.32872	9.516 8236

Examples in Use of Table 2, above.

Ex. 1.—From Tables 2 and 1, find the hydraulic radius r , $\sqrt{r}$, and $a\sqrt{r}$ (a = area of section considered) for the Catenary, (1) whose vertical diameter is 8 ft. 3 ins., and (2) whose horizontal diameter is 7 ft. 4 ins.?

Solution.—For (1), vert. dia. of 8 ft. 3 ins., we have, $r = 2.063 \times 0.9269 = 1.912$, $\sqrt{r} = 1.436 \times 0.9628 = 1.383$, $a\sqrt{r} = 76.77 \times 0.8615 = 66.14$; and for (2), hor. dia. of 7 ft. 4 ins., we have, $r = 1.833 \times 1.043 = 1.912$, $\sqrt{r} = 1.354 \times 1.0211 = 1.383$, $a\sqrt{r} = 57.19 \times 1.1564 = 66.13$ +.

Comparing the above results it is found that they are equal, simply because 7 ft. 4 ins. (= 88 ins.) is the hor. dia. of a catenary whose vert. dia. is 8 ft. 3 ins. (= 99 ins.); i.e., the hor. dia. of catenary = ¾ vert. dia. See Table 5 following.

Ex. 2.—In Kutter's formula, $v = c\sqrt{rs} = c\sqrt{r} \sqrt{s}$, it is required to find the velocity v of flow in an Egg-shaped sewer whose hor. dia. is 4 ft. 6 ins., flowing ¾ full depth, and on a grade of $s = .0004$, assuming the value of coefficient $c = 100$?

Solution.—From Tables 1 and 2, preceding, the value of $\sqrt{r} = 1.061 \times 1.1237 = 1.192$; hence the velocity of flow is $v = 100 \times 1.192 \times .02 = 2.384$ ft. per sec.

Ex. 3.—In Kutter's formula, $q = av = c \cdot a\sqrt{r} \cdot \sqrt{s}$, it is required to find the discharge from a Basket-Handle conduit whose vert. dia. is 8 ft., flowing full, and on a grade of .000225, assuming the value of roughness $n = .015$.

Solution.— $s = .000225$, and $\sqrt{s} = .015$. From Tables 1 and 2, $r = 2 \times .9857 = 1.9714$, and $a\sqrt{r} = 71.09 \times .9939 = 70.66$. The value of c is obtained from Table 8, page 1171, and $= 111$. Hence, the discharge $q = 111 \times 70.66 \times .015 = 117.6$ cu. ft. per sec.

3.—VELOCITIES IN FEET PER SECOND IN CIRCULAR BRICK SEWERS.*

By Kutter's Formula, using $n = 0.015$.

(Slope $s =$ value in first column $\div 100$.)

Fall in Ft. per 100 Ft. (100 s)	Diameter of Pipe or Sewer, in Feet.											$\sqrt{s}$

*For second-class brick, dressed stone, or tuberculated iron. (See Table 9.)

Note.—Velocities in table are equal to $c\sqrt{r} \times \sqrt{s}$; $c\sqrt{r}$ is in the next line to bottom for the particular diameter of pipe, and $\sqrt{s}$ is found in the last column.

$\frac{1}{a}$ —area of section in sq. ft.; r —hydraulic radius in ft.; c —coefficient in Kutter's formula, using mean value of $s = .001$. Velocity in ft. per sec. $= v = c\sqrt{rs} = c\sqrt{r} \sqrt{s}$. Discharge in cu. ft. per sec. $= q = av = ac\sqrt{rs} = ac\sqrt{r} \sqrt{s}$.

4.—PROPERTIES OF CIRCULAR- CONDUITS OR SEWERS.

(a) General.

When flowing full:

$$a = \frac{\pi d^2}{4},$$

$$= 0.7854d^2.$$

$$p = \pi d,$$

$$= 3.1416d.$$

$$r = \frac{d}{4}.$$

When flowing $\frac{1}{2}$ full:

$$a = \frac{\pi d^2}{8},$$

$$= 0.3927d^2.$$

$$p = \frac{\pi d}{2},$$

$$= 1.5708d.$$

$$r = \frac{d}{4}.$$

In which

a = area in sq. ft.
 p = wetted perimeter in ft.
 r = hydraulic radius in ft.
 $\text{Log } \pi = 0.4971499.$

$$\text{Log } \frac{\pi}{4} = 9.8950899.$$

Fig. 4.—Ratios of a , v , and q for Filled Segments.
 (a , v or q = unity when section is full.)

Notation.— a —sectional area of wetted section of sewer, in square feet;
 r —hydraulic mean radius; c —coefficient in Kutter's formula, using mean
value of $s = .001$. Velocity $v = c\sqrt{r} \times \sqrt{s}$ for the particular diameter d , and
the particular grade or slope s .

Example in Use of Table 9, preceding.

Example.—What size of egg-shaped sewer, running two-thirds full depth, on grade of one-tenth of one per cent., will carry 16 cu. ft. per second, assuming $n = 0.015$?

Solution.—From the preceding table, for "Flowing two-thirds full depth" we select, if possible, the width d_1 whose velocity multiplied by the corresponding area a will give the discharge q ($=av$) = 16, for a grade of 0.1 ft. per 100 ft. Now for $d_1 = 2$ ft., $q = 3.023 \times 2.26 = 6.83$ cu. ft. per sec.; and for $d_1 = 3$ ft., $q = 6.802 \times 3.01 = 20.47$ cu. ft. per sec. Hence, by proportion, for $q = 16$, $d_1 = 2.67$ ft. or, say, 2 ft. 8 ins.; and the height $d_2 = 1\frac{1}{2}d_1 = 4$ ft. (See Table 8.) In practice it is customary to increase the calculated diameter by about 2 ins., more or less.

Thickness of Brick Sewer Walls.—No fixed rule can be used, but for brick sewers under 30 ins. in diameter a single 4-in. ring will generally suffice. Two rings (2×4 ins.) of brick are required for diameters from 2½ to 6 ft.; and three rings from about 6 to 10 ft. Above 10 ft. diameter treat sewer above spring line as a masonry arch, and keep the line of resultant pressure well within the middle third. Baldwin Latham gives the following formula for thickness:

$$t = \frac{dr}{100} \dots \dots \dots (1)$$

where t = thickness of brick wall, in feet;

d = depth of excavation, in feet;

r = radius of sewer, in feet.

It is essential that sewer linings be water tight.

Sewer Foundations.—Many sewers are rendered leaky and unsanitary by reason of their having been constructed on improper foundations. An economical foundation for sewers projected through soft, marshy ground consists of two-pile bents driven say 4 or 5 feet apart, capped with suitable cross timbers, on top of which are laid the thick longitudinal floor planking, forming a platform for the sewer proper. Sometimes the piling supporting the platform is omitted. Timber foundations should always be below the ground-water level to prevent decay.

Sizes 18-in. and under in 2½-foot lengths, sizes 21-in. and over in 3-foot lengths, improved corrugated deep sockets and corrugated ends.

Discount on application.

Kinds of Sewers.—Sewers may be classified according to the special purposes for which they are designed or according to the material entering into their construction. Thus we have branch sewers, main-line sewers, intercepting sewers, trunk-line sewers, and outfall sewers. Trunk-line sewers are often projected through several towns, the expense being borne proportionately. An outfall sewer is the main stem of discharge to the outlet. Small sewers are built of terra cotta pipe, cast iron pipe, concrete pipe, etc.; the larger sewers are constructed of brick, concrete, reinforced concrete, etc. Wood-stave pipe enters into the design of the outfall sewer of the City of Los Angeles, projected as follows: 2400 ft. of 52-in. circular brick conduit; 4,400 ft. of 40-in. circular brick conduit; 16,900 ft. of inverted syphon of 38-in. wood-stave pipe; 1,900 ft. of 40-in. circular brick

conduit; 5,800 ft. of 6-ft. oval brick and concrete tunnel; 800 ft. of 40-in. circular brick conduit; 19,100 ft. of inverted syphon of 36-in. wood-stave pipe; 12,100 ft. of 40-in. circular brick conduit; 900 ft. of 6-ft. oval brick and concrete tunnel; 600 ft. of 40-in. circular brick conduit; 1,300 ft. of 6-ft. oval brick and concrete tunnel; 1,100 ft. of 24-in. cast iron pipe, to outlet in Pacific Ocean.

Location of Sewers.—Sewers are most commonly located under the centers of streets, or on either side of broad avenues. Some cities however prefer to build only one sewer near one curb, in streets of ordinary width. In cities where alleys exist, the latter are often selected for the sewer lines.

Manholes are street openings to sewers; they are built for inspection and cleaning of sewers, and for ventilation. Those systems of sewers which have been built without manholes are certainly at a disadvantage. For large sewers the manholes are built tangent to one side of sewer, in the form of a conic frustum; or, an entrance to side of sewer may be made by a slanting shaft with steps for descent, with a manhole entrance at top of steps. Manholes should be situated at bends of both alignment and grade of the sewer, so that a clean sight may be had through the sewer from one manhole to another. If this is impracticable by reason of the expense, *lamp-holes* may be substituted for them occasionally. These latter consist of a small circular shaft from the street to the top of sewer through which a lamp may be suspended to be sighted at from the nearest manhole in either direction. Fig. 10 shows a section of a circular manhole frame and cover, to be set flush with the street surface.

Fig. 10.—Manhole.

Catch Basins are placed along the gutters at the sides of streets, and especially at street corners, to act as settling basins for surface waters containing sand and dirt. The outlet from the catch basin to the sewer is near the top of the basin. They should be cleaned out before the deposit becomes too great. The styles used are innumerable. That shown in Fig. 11 is

Fig. 11.—Catch Basin.

manufactured by James B. Clow & Sons, of Chicago, and is designed for street corners.

The Wear of Sewer Inverts (By E. A. Hermann. Eng. News, Feb. 4, 1904).—The materials most commonly used for sewer construction are vitrified clay pipe, vitrified brick, common building brick (more or less unburned), and concrete. In the sewers of St. Louis, which are on the combined system, the grades range from 0.2% to 2%, average about 0.5% for sewers more than 5 ft. in diameter and about 1% for the smaller sewers. The vitrified clay pipes show no appreciable wear after about 35 years' use; these sewers are mostly laterals, and have, of course, the smallest discharge, though some of those in the business and manufacturing sections of the city carry a constant stream from 1 to 3 ins. deep, containing more or less acids, scalding hot water and steam. The pipes vary from 12 to 24 ins. in dia., except a few lines, which are 30 to 36 ins. in dia. The vitrified brick (in use about 12 years) also shows no appreciable wear. The inverts of sewers built of common brick begin to show some wear after about 3 years of service, and after about 30 years' use the first ring of brick is worn away from 2 ins. to nearly its whole depth of 4 ins. This wear varies greatly in sewers of different size, grade, quantity and quality of sewage, and hardness of brick; the average life of such brick appears to be about 40 years. Illustrations: Method employed in repairing badly worn sewer inverts; section of large sewer at St. Louis, Mo.

A New Jointing Material—Sulphur and Sand—for Sewer Pipes (By Alex. Potter. Eng. News, Mar. 10, 1904).—The following table gives information concerning the cost and amount of material in making sulphur-sand joints:

APPROXIMATE COSTS.

Size of Pipe.	Amt. of Mixture Lbs. per Joint.	Mixture	Gasket.	Fuel.	Labor.	Total.	Per foot Lengths.	
							3-Ft.	2-Ft.
24-in.	10.0	.125	.02	.02	.13	.295	.10	.15
22-in.	9.0	.1125	.02	.02	.13	.282	.095	.14
20-in.	8.0	.10	.02	.02	.12	.260	.09	.13
18-in.	7.0	.087	.02	.02	.11	.247	.08	.12
15-in.	5.5	.069	.01	.01	.10	.187	.065	.095
12-in.	4.2	.052	.01	.01	.09	.162	.055	.08
10-in.	3.3	.041	.01	.01	.08	.141	.045	.07
8-in.	2.5	.031	.01	.01	.07	.121	.04	.06

The exclusion of ground water will increase the capacity of the sewer from 10% to 100% through territory subject to the admission of ground water, so that the increase in cost becomes a trifling matter, especially when it is considered that tree roots are kept out of the sewer.

Refuse Destructor Combined With Electric Light Plant at West-mount, P. Q. (Eng. News, May 24, 1906).—Table of estimated costs.

Specifications for Refuse Destructor, Borough of Richmond, New York City (Eng. News, Dec. 6, 1906).—The first thorough-going, if not absolutely the first, specifications and call for bids for a refuse destructor designed to produce heat for lighting or power purposes in the U. S.

Cost of Shallow and Deep Sewer Trenches (By J. G. Palmer. Eng. News, June 25, 1908).—Cost-data tables.

Principles of Sewage Purification on Land (By Rudolph Hering. Eng. News, May 27 and June 3, 1909).

Rainfall, and Run-Off in Storm-Water Sewers (By C. C. Gregory. Trans. A. S. C. E., Vol. LVIII).—Formulas, diagrams and tables. Table 1, Comparison of rainfall and discharge from the 6th Avenue sewer, N. Y. City, the drainage area of which is 221 acres; Table 2, Short-time storms; Table 3, Long-time storms.

Cost of a 66-Inch Brick Sewer at Gary, Ind. (By E. M. Scheflow. Eng. Rec., Jan. 2, 1909).—Total cost of sewer per lin. ft.: Excavation by machine; \$0.508; excavation by hand, \$1.25; pumping, \$1.61; sheeting, \$0.358.

laying, \$1.32; backfilling by machine, \$0.406; backfilling by hand, \$0.136; hauling material, \$0.607; superintendence and general, \$0.30; materials, \$1.81; depreciation of machinery, repairs and the like (estimated), \$1.50; total, \$10.122.

Louisville Sewerage Improvements (By R. DeL. French. Eng. News, Oct. 14, 1909).—Illustrated:—Standard sections of circular concrete sewers, with table of dimensions and quantities, for hard and soft ground; Typical horseshoe section of reinforced-concrete sewer, 15 ft. high; Typical semi-elliptical section of reinforced concrete sewer, 10 ft. high; Typical junction chamber, reinforced-concrete sewers; Combined sewer and drain.

Aerial Distribution of Sewage over Percolating Filters (By Wm. Gavin Taylor. Eng. News, Nov. 11, 1909).—Illustrations of nozzle; diagrams of distribution effected by same; pressure undulating valves, described and illustrated.

The Improved Water and Sewerage Works of Columbus, O. (By J. H. Gregory. Trans. A. S. C. E., Vol. LXVII., June, 1910).—Illustrations: Lime saturators; mixing tanks; sewage pumping station; purification works; septic tanks; gate house; etc.

Modern Procedure in District Sewer Design (By W. W. Horner. Eng. News, Sept. 29, 1910).—Diagrams: (a) Rainfall curves for St. Louis; (b) Approximate curves for designing vitrified pipe and circular egg-shaped sewers under 60 ins. mean diameter; (c) Approximate curves for designing circular sewers 4 to 24 ft. in diameter; (d) Capacities of standard horse-shoe sewer. Illustrations: Details of sewer inlets. Table: Data for branch sewer.

66.—IRRIGATION.

General Discussion.—Those who are specially interested in irrigation matters will find much valuable information in the Bulletins issued by the U. S. Department of Agriculture, and in the Water-Supply and Irrigation Papers, Annual Reports, etc., of the U. S. Geological Survey. Lists of the various Documents may be had on application, and the papers are generally for free distribution.

The Problems of Irrigation are broad and intricate, the local conditions of soil, water, climate, crops, etc., requiring much study, often extending over considerable periods of time. The amount of water required will depend upon the kind of crops, as well as upon the soil, and to a certain extent upon the climate; also upon the amount of seepage and evaporation before it reaches the land to be irrigated; and last of all upon the method of irrigation, which may be more or less wasteful. If there is any rainfall, the records of monthly precipitation, extending over say 15 to 20 years, should be examined for one-, two- and three- year periods of greatest drought, for a possible reduction in the artificial supply. (See Water Supply, page 1194.)

The Unit of Land Area in irrigation is the acre, equal to 43560 sq. ft. A square 1-acre tract is 208.71 ft. square; a square 2-acre tract is 295.16 ft. square; a square 3-acre tract is 361.50 ft. square; a square 4-acre tract is 417.42 ft. square; a square 5-acre tract is 466.69 ft. square; a square 10-acre tract is 660 ft. square = $\frac{1}{4}$ mile square; a square 20-acre tract is 933.38 ft. square; a square 40-acre tract is 1320 ft. square = $\frac{1}{2}$ mile square; a square 80-acre tract is 1866.76 ft. square; a square 160-acre tract is 2640 ft. square = $\frac{1}{2}$ mile square.

The Units of Flow of water are the "inch" (miner's inch) and the cubic foot per second.

The "Inch" is the volume of water (say in cubic feet) which will flow through a vertical standard orifice one-inch square (say in one minute) under a given pressure head (say 5 to 6 $\frac{1}{2}$ inches, and fixed by State law). This amounts to about 1.5 cubic feet per minute (see Table 1). The "inch" is convenient in delivering water to small users because the quantity being delivered is apparent at a glance. Where the delivery calls for more than one "inch" a box is constructed with a long horizontal slot one inch or more in height and provided with a slide and scale.* By manipulating the slide, the slot may be elongated so as to deliver the number of inches required; but as the end contractions remain constant it is apparent that the rate of discharge increases faster than the scale readings indicate.

Table 1 is based on one "inch" discharging 1.5 cu. ft. per min.

1.—EQUIVALENTS OF DISCHARGE OF 1 "INCH," AT 1.5 CU. FT. PER MIN.

Duration of Flow	U. S. Gallons.	Cubic Feet.	Tons of 2000 Lbs.	Acre-Ins.	Acre-Ft.
1 Second.....	.187	0.025	.00078	.0000069	.00000057
1 Minute.....	11.221	1.5	.0469	.0004132	.00003444
1 Hour.....	673.25	90.	2.8125	.024793	.0020661

1 30-Day Month.....	484738.	64800.	2025.	17.851	1.4876

Note.—1 cu. ft. = 7.48052 U. S. liquid gallons = .03125 tons (at 62.5 lbs. per cu. ft) = .000 275 4821 acre-in. = .000 022 956 84 acre-ft.

The Cubic Foot per Second is a unit rate of flow, used mainly in gaging streams and canals. It is definite, whereas the "Inch" is more or less indefinite. Note that both the "Inch" and the Cu. Ft. per Sec. are rates of

* See Foot-note on following page.

*flow, and that where definite *quantities* are demanded the element of *time* should be included, as 10 "inches" for one month, or 0.25 cu. ft. per sec. for one month, etc. (See Tables 1 and 2.) Contracts for water based on any fixed number of cu. ft. per sec. throughout the season are unfair to the user, or wasteful, or both. There are many and various recording instruments on the market for determining the rates of discharge. They are self-registering and consist usually of a fluctuating line drawn on profile paper wound around a cylinder, by a pen- or pencil point traveling longitudinally to represent the time, and by the cylinder oscillating as the water rises or falls in the measuring chamber, in which a float is connected with the instrument.

2.—EQUIVALENTS OF DISCHARGE OF 1 CUBIC FOOT PER SECOND.

(1 cu. ft. per sec. = about 40 "inches.")

Duration of Flow.	U. S. Gallons.	Cubic Feet.	Tons of 2000 Lbs.	Acre-Inch.	Acre-Ft.
1 Second.....	7.48	1	.031	.00028	.000023

1 30-Day Month.....	19 389 508.	2 592 000	81 000.	714.05	59.504

Note.—1 cu. ft. = 7.48052 U. S. liquid gallons = .03125 tons (at 62.5 lbs. per cu. ft.) = .000 275 4821 acre-in. = .0000 229 5684 acre-ft.

The Units of Volume of water are the Acre-Foot and the Acre-Inch, the latter being only occasionally used, and $\frac{1}{12}$ of the former.

The Acre-Foot is the volume of water which will cover an acre 1 ft. deep = 43560 cu. ft. Mr. Elwood Mead says of this unit:

It is a convenient unit for selling stored water, since the capacity of reservoirs can be measured by the same unit. Contracts in which the acre-foot is used provide for the delivery of water on the demand of the irrigator, or at intervals rather than in continuous flow, and canal companies have hesitated about adopting this unit because of a fear that satisfactory arrangements for delivery could not be made, but that more water would be called for at some time than the canal could supply, while at other times the entire volume would run to waste. Wherever the acre-foot has been adopted it has proved acceptable to irrigators, because they share in the benefit resulting from care and skill in distribution.

Table 3 gives the rates of flow equivalent to an acre-ft. in a 24-hour day, and Table 4 gives the rates of flow equivalent to an acre-ft. in a 30-day month.

3.—RATES OF FLOW FOR DISCHARGE OF 1 ACRE-FOOT IN 1 DAY (24 Hours).

(For 1 acre-inch, divide by 12.)

* Water sold by the inch by any individual or corporation shall be measured as follows, to wit: Every inch shall be considered equal to an inch-square orifice under a five-inch pressure, and a five-inch pressure shall be from the top of the orifice of the box put into the banks of the ditch to the surface of the water. Said boxes or any slot or aperture through which such water shall be measured shall in all cases be six inches perpendicular, inside measurement, except boxes delivering less than twelve inches, which may be square, with or without slides. All slides for the same shall move horizontally, and not otherwise, and said box put into the banks of ditch shall have a descending grade from the water in ditch of not less than one-eighth of an inch to the foot. (General Statutes of Colorado, sec. 3472.)

4.—RATES OF FLOW FOR DISCHARGE OF 1 ACRE-FOOT IN 1 MONTH (30 Days).

(For 1 acre-inch, divide by 12.)

The Duty of Water is the amount of land which a unit volume of water, properly applied, can irrigate; or, conversely, it is *measured* by the amount of water required to irrigate one acre of land. This amount of water may be measured by volume, as in storage, or by (average) flow, as in distribution.

The (miner's) "Inch" is often cited by many irrigators as the amount required for one acre, and by others as the amount required for two, or even three, acres of land. By referring to Table 1, preceding, it can readily be seen that a flow of 1 "inch" is equal to about 1.5 acre-ft. per month. If flowing constantly this would amount to about 6 acre-ft. for an irrigation period of 4 months (say from May 15 to September 15), and about 7.5 acre-ft. for an irrigation period of 5 months (say from May 1 to October 1). For shorter periods it would be proportionately less. In the Rocky Mountain regions the irrigation season ranges from 100 to 150 days; in parts of Southern California it is used throughout the year; while in the colder climates, as in some parts of Montana, the period is often shortened to two months.

Assuming that a continuous (average) flow of one "inch," throughout the irrigation season, will irrigate $1\frac{1}{2}$ acres, then from Table 1 this is equivalent to 1 cu. ft. per sec. for $\left(1\frac{1}{2} \times \frac{1}{.025} - \right)$ 70 acres of land. If the length

of irrigation season is 120 days, this would amount to $\left(\frac{59.504 \times 4}{70} - \right)$ 3.4

acre-ft. per acre. Similarly, the equivalents in cu. ft. per sec. and in acre-ft. can be found for any other assumed duty in acreage per "inch."

The Cu. Ft. per Sec. is another unit of flow in measuring the duty of water. Assuming 1 cu. ft. per sec. will irrigate 60 acres, we see by Table 2 that this is equivalent to 59.5 acre-ft. per month, or about 1 acre-ft. per acre per month, or 4 acre-ft. per acre for 4-months period of irrigation.

Again, assuming 1 cu. ft. per sec. for 80 acres, we would require $\frac{59.504}{80}$ or

about $\frac{3}{4}$ acre-ft. per acre per month, or 3 acre-ft. per acre for 4-months period of irrigation.

The Acre-Foot is now generally conceded to be the best duty unit by most experts in irrigation, but it must be admitted that the "Inch" and the Cu. Ft. per Sec. have some merits as supplementary factors. The acre-ft. is a definite quantity both in volume (43560 cu. ft.) and in depth of equivalent precipitation (12 ins.); and by the use of the preceding tables, it is easily converted into other units. It is well to remember that 1 cu. ft. per sec. = about 40 "inches" = about 2 acre-ft. per 24-hour day = about 60 acre-ft. per month. One great advantage of the acre-ft. is that it is convenient to apply in measuring the storage or source of water supply, as well as the direct quantity required in irrigation, the contents of reservoirs being stated usually in acre-ft. = total storage capacity in cu. ft. divided by 43560.

Tables 5, 6, 7 and 8, following, are from Experiment Stations Bulletin 86, U. S. Dept. of Agriculture. The first three tables show the duty of water under varying conditions, while Table 8 shows the length of the irrigation seasons.

Table 9, following, is from King's "Irrigation and Drainage," the second column having been adopted by King from Wilson's "Manual of Irrigation Engineering," and includes all losses from the head of the canals:

9.—DUTY OF 1 CU. FT. PER SEC., AND NO. OF "INCHES" IN 10 DAYS, IN VARIOUS COUNTRIES.

Name of Country.	No. of Acres per Second-Foot.	No. of Inches per 10 Days.
Northern India.....	60 to 150	3.967 to 1.587
Italy.....	65 to 70	3.661 to 3.4
Colorado.....	80 to 120	2.975 to 1.983
Utah.....	60 to 120	3.967 to 1.983
Montana.....	80 to 100	2.975 to 2.38
Wyoming.....	70 to 90	3.4 to 2.644
Idaho.....	60 to 80	3.967 to 2.975
New Mexico.....	60 to 80	3.967 to 2.975
Southern Arizona.....	100 to 150	2.38 to 1.587
San Joaquin Valley.....	100 to 150	2.38 to 1.587
*Southern California.....	150 to 300	1.587 to 0.793

* The comparatively high duty of water in California is due to the extra care taken in construction of conduits to prevent losses, and to economy of distribution.

Canals.—Canals in earth are usually made wide and shallow with side slopes varying from $\frac{1}{2}$ to 2 horizontal on 1 vertical. It is best to select such side slopes, depending on the earthy material, as will be maintained during flow. The cross-section of a canal is determined often by the allowable velocity which may not exceed, ordinarily, about 2 $\frac{1}{2}$ feet per second in ordinary soils. If the soil is light 2 ft. is about the maximum, while if hard and gravelly 3 or 4 feet may be exceeded. The velocity of flow in a canal is dependent on the hydraulic radius, the grade or slope, and the roughness n of wetted surfaces (see Kutter's formula, page 1167). Canals with rubble-, concrete- or cement lining are often used where water is scarce and valuable.

In estimating the flow by Kutter's formula, use $n = .0225$ for ordinary earthen canal with clean bed, and $n = .035$ for bed in bad order having stones and weeds in great quantities. (See page 1168.)

Wilson, in his *Manual of Irrigation Engineering*, gives the following data relative to some great perennial canals:

10.—DATA ON SOME GREAT PERENNIAL CANALS.
(See Wilson's *Manual of Irrigation* for full and extended data.)

Del Monte Canal.....	"	50	2400	1 " 2112	65	5.5

Conduits and Flumes frequently take the place of canals even in localities other than at crossing of streams. The flumes are usually constructed of wood (sometimes of steel), generally rectangular in cross-section, and supported on trestle work of the same material as the flume. The V-shaped flume is seldom used in connection with large irrigation projects, unless combined with logging. The semi-circular flume, of wood-stave pipe construction, or of steel, has the merit of giving the maximum velocity of

flow for a given area of wetted cross-section. Pipe lines of wooden staves or of steel are frequently used as inverted syphons for conveying water across valleys where cost of flumes on high trestles would be very expensive. Wooden flumes may be made tight (1) by tangential compressive forces as with adjustable rods or wedges; (2) by caulking and tarring the joints; (3) by using two thicknesses of siding and bottom plank with tarred paper between. Steel flumes are caulked similarly to riveted steel pipe.

Earthwork Diagrams for Estimating Quantities in Small Irrigation Canals in Level Sections (Eng. News, June 10, 1909).

Cost of a Large Irrigation Canal (Eng. Rec., Jan. 2, 1909).—Table of unit costs on about 4,400 ft. of the south canal of the Uncompahgre Project of the U. S. Recl. Serv. The canal has a bottom width of 40 ft., side slopes of 2 to 1, and a depth of water of 8.3 ft.

Field Work in Locating Irrigation Ditch and Canal Lines (By A. B. Bartlett. Eng. News, May 26 1910).—**Small Ditches:** Ditches designed to irrigate 100 to 200 acres may be laid out by setting stakes on the lower side of the ditch, determined by the level only. Ditches 5 to 10 ft. on the bottom

and 1 to 3 ft. deep require more care: the slope stakes on the lower side of the ditch are set first for about 1,500 ft., after which they are lined up by eye to tangents and curves nearly conforming to the contour which the slope stake on the lower side of the ditch would naturally follow, but improving on this alinement by increasing or decreasing the cut in order to have good curves and tangents, etc. Ditches over 10 to 12 ft. on the bottom generally require the methods of railway location and cross-sectioning. **Side Slopes.** Lower side of ditch, from 1 on 1½ to 1 on 3 in excavation, and from 1 on 2 to 1 on 4 for fill on lower bank. On side-hill work, cut on upper side of ditch is made from 1 on 1 to 1 on 2, for earth. **Greatest velocities**, in feet per second, permissible in different classes of material are as follows: Sandy soil, 1.3; loose gravelly soil, 2.5; firm soil and firm sandy loam, 3.0; gravel, 3.6; firm gravelly soil, 5.3; loose rock and shale, 6.0 to 7.0; solid rock, 7.0 to 15.0. **Kutter's formula:** Use $n=0.03$ or 0.025 for clean ditches in ordinary earth.

Drainage of Irrigated Lands with Special Reference to Experiments in Utah (By C. F. Brown. Farmers' Bulletin No. 371, U. S. Dept. of Agric., Oct. 2, 1909; Eng. News, Oct. 13, 1910).—Illustrations: (1) Method of grading drainage trench; (2) Plan of drainage; (3) Box drains with and without bottoms; (4) Relief well and method of laying box drain through soft ground. The tract drained consisted of 31.6 acres. **Cost.**—Tile (1000' of 10" @ \$0.18½ = \$182.50, 1012' of 8" @ \$0.12 = \$121.14, 330' of 8" @ \$0.06 = \$19.80, 650' of 5" @ \$0.058 = \$37.70, 2 6" on 8" wyes @ \$0.72 = \$1.44) \$362.88; Hauling (30 tons 1½ miles @ \$0.30 per ton-mile) \$13.50; Digging (134 rods @ \$0.52 = \$69.68, and 42 rods @ \$0.40 = \$16.80) \$86.48; Laying tile, \$18.75; Filling trench, \$10.00. Total cost, \$491.61 = \$15.60 per acre. Labor, \$2 per 10 hours; tile layers, \$2.50; man with team, \$3 per day.

67.—WATERWAYS.*

The Suez Canal, connecting the Mediterranean and Red Seas, was begun in 1859 and completed in 1869. Its total length is 90 miles, of which about two-thirds is through shallow lakes. The material excavated was usually sand, though in some cases strata of solid rock from 2 to 3 feet in thickness were encountered. The total excavation was about 80,000,000 cubic yards under the original plan, which gave a depth of 25 feet. In 1895 the canal was so enlarged as to give a depth of 31 feet, a width at bottom of 108 feet and at the surface of 420 feet. The original cost was \$95,000,000, and for the canal in its present form slightly in excess of \$100,000,000. The canal is without locks, being at the sea level the entire distance. The length of time occupied in passing through the canal averages about 18 hours. By the use of electric lights throughout the entire length of the canal, passages are made at night with nearly equal facility to that of the day. The tolls charged are 8.50 francs per ton net register, "Danube measurement," which amounts to about \$2 per ton United States measurement. Steam vessels passing through the canal are propelled by their own power. Since Jan. 1, 1902, the minimum draft of water has been raised to 26' 3" (8 meters).

Table 1, next page, shows the number and tonnage of vessels which passed through the Suez Canal, together with the transit receipts for same, and also the number of passengers carried, from its opening until 1903.

The Cronstadt and St. Petersburg Canal, connecting the bay of Cronstadt with St. Petersburg, is a work of great strategic and commercial importance to Russia. The canal and sailing course in the bay of Cronstadt are about 16 miles long, the canal proper being about 6 miles and the bay channel about 10 miles, and they together extend from Cronstadt, on the Gulf of Finland, to St. Petersburg. The canal was opened in 1890 with a navigable depth of 20½ feet, the original depth having been about 9 feet. The width ranges from 220 to 350 feet. The total cost is estimated at about \$10,000,000. There are no locks.

The Corinth Canal, connecting the Gulf of Corinth with the Gulf of Ægina, reduces the distance from Adriatic ports about 175 miles and from Mediterranean ports about 100 miles. Its length is about 4 miles, a part of which was cut through granitic soft rock and the remainder through soil. There are no locks, as is also the case in both the Suez and Cronstadt canals, described above. The width of the canal is 72 feet at bottom and the depth 26½ feet. The work was begun in 1884 and completed in 1893, at a cost of about \$5,000,000. The average tolls are 18 cents per ton and 20 cents per passenger.

The Manchester Ship Canal, connecting Manchester, England, with the Mersey River, Liverpool, and the Atlantic Ocean, was opened for traffic January 1, 1894. The length of the canal is 35½ miles, the total rise from the water level to Manchester being 60 feet, which is divided between four sets of locks, giving an average to each of 15 feet. The minimum width is 120 feet at the bottom and averages 175 feet at the water level, though in places the width is extended to 230 feet. The minimum depth is 26 feet, and the time required for navigating the canal from 5 to 8 hours. The total amount of excavation in the canal and docks was about 45,000,000 cubic yards, of which about one-fourth was sandstone rock. The lock gates are operated by hydraulic power. Railways and bridges crossing the route of the canal have been raised to give a height of 75 feet to vessels traversing the canal, and an ordinary canal whose route it crosses is carried across by a springing aqueduct composed of an iron caisson resting upon a pivot pier. The total cost of the canal is given at \$75,000,000.

* Much of the information relating to large ship canals is from *Great Canals of the World*, 1905, Department of Commerce and Labor, Washington, D. C. Those who are particularly interested in this subject should consult the "List of Works Relating to Deep Waterways from the Great Lakes to the Atlantic Ocean with some other related works," published by Supt. of Documents, Washington, D. C.

The Kaiser Wilhelm Canal. Two canals connect the Baltic and North Seas through Germany; the first, known as the Kaiser Wilhelm Canal, having been begun in 1887 and completed in 1895 and constructed largely for military and naval purposes, but proving also of great value to general mercantile traffic. The length of the canal is 61 miles, the terminus in the Baltic Sea being at the harbor of Kiel. The depth is 29½ feet, the width at the bottom 72 feet, and the minimum width at the surface 190 feet. The route lies chiefly through marshes and shallow lakes and among river valleys. The total excavation amounted to about 100,000,000 cubic yards, and the cost to about \$40,000,000.

The Elbe and Trave Canal, the second canal connecting the Baltic and North Seas through Germany, is smaller than the Kaiser Wilhelm Canal. It was opened in 1900, with a length of about 41 miles and a depth of about 10 feet. It is described in the International Yearbook, 1900, as follows:

"The Elbe and Trave Canal, in Germany, was opened by the Emperor of Germany on June 16, 1900. It has been under construction for five years, and has cost about \$5,831,000, of which Prussia contributed \$1,785,000 and the old Hanse town of Lubek \$4,046,000. The length of the new canal is about 41 miles, and is the second to join the North Sea and the Baltic, following the Kaiser Wilhelm Canal (or Kiel Canal), built about five years ago at a cost of \$37,128,000. The breadth of the new canal is 72 feet; breadth of the locks, 46 feet; length of locks, 261 feet; depth of locks, 8 feet 2 inches. It is crossed by 29 bridges, erected at a cost of \$1,000,000. There are seven locks, five being between Lubek and the Molner See (the summit point of the canal) and two between Molner See and Fauenberg-on-the-Elbe. At this point it may be noted that the Germans began experiments during 1900 with electric towing on the Flinow Canal between Berlin and Stettin. A track of 1-meter gauge was laid along the bank of the canal, having one 9-pound and one 13-pound rail laid partly on cross ties and partly on concrete blocks. The larger rail serves for the return current, and has bolted to it a rack which gears with a spur wheel on the locomotive. The locomotive is 6 feet 10 inches by 4 feet 10 inches, mounted on four wheels, with a wheel base of 3 feet 6 inches, and weighing 2 tons. It is fitted with a 12-horsepower motor, current for which is furnished by a 9-kilowatt dynamo, driven by a 15-horsepower engine. The current is 500 volts, and is transmitted by a wire carried on wooden poles 23 feet high and about 120 feet apart. The boats are about 132 feet long and 15 feet 6 inches beam, and carry from 150 to 175 tons on a draft of 4 feet 9 inches. During 1900 the Stettin-Swinemund Canal, with a length of 35 miles, has been dredged throughout, and is now open to steamers drawing 22 feet of water. Swinemund is on the Baltic Sea. Among the various projects for European canals may be mentioned one connecting the Danube a little below Vienna, Austria, with the Adriatic Sea at Trieste, a distance of about 319 miles. Herr Wagentahner, of Vienna, is said to have the concession for this canal, the construction of which will cost some \$120,000,000. Late in 1900 a canal from Liege to Antwerp, in Belgium, was being seriously discussed, in order to connect the prosperous city of Liege with the sea, and make it, like the city of Manchester, England, a seaport. The original promoter of the scheme was Mr. Joseph Redouti, who is now dead. Mr. Redouti's plans have recently been put in practical shape by Louis Hubin and Gaston Deville, who propose a canal 84 miles long, 200 feet wide, and 23 feet deep from Antwerp to Liege, with locks at Liege, Hasselt, Herenthals, and Antwerp. The difference in level to be overcome by locks would be 175 feet, and it is thought that thirteen single locks and one double lock would be sufficient. The total estimated cost of the work is \$25,200,000."

The Welland Canal connects Lake Ontario and Lake Erie on the Canadian side of the river. It was constructed in 1833 and enlarged in 1871 and again in 1900. The length of the canal is 26½ miles, the number of locks 26, the size of locks 270 by 45 feet, the total rise of lockage 326½ feet, and the total cost about \$25,000,000. The annual collection of tolls on freight, passengers, and vessels averaged about \$225,000 and the canal is open on an average about 240 days in a year. By order in council dated April 27, 1903, the levy of tolls for passage through Dominion canals has been abolished for a period of two seasons of navigation.

The Sault Ste. Marie Canals, at Sault Ste. Marie, Mich., and Ontario are located adjacent to the falls of the St. Marys River, which connects Lake Superior with Lake Huron, and lower and raise vessels from one level to the other, a height of 17 to 20 feet.

The canal belonging to the United States was begun in 1853 by the State of Michigan and opened in 1855, the length of the canal being 5,674 feet, and provided with two tandem locks, each being 350 feet in length and 70 feet wide, and allowing passage of vessels drawing 12 feet, the original cost being \$1,000,000. The United States Government, by consent of the State, began in 1870 to enlarge the canal, and by 1881 had increased

its length to 1.6 miles, its width to an average of 160 feet, and its depth to 16 feet; also had built a single lock 515 feet long and 80 feet wide, with a depth of 17 feet on the sills, which was located 100 feet south of the State locks. The State relinquished all control of the canal in March, 1882. In 1887 the State locks were torn down and replaced by a single lock 800 feet long, 100 feet wide, and a depth of 22 feet of water on the sills. This lock was put in commission in 1896. The canal was also deepened to 25 feet.

The canal on the Canadian side, on the north side of the river, is 1 miles long, 150 feet wide, and 22 feet deep, with lock 900 feet long, 60 feet wide, with 22 feet on the miter sills, and was built during the years 1888 to 1895.

Canadian Canal Systems.—The canal systems of the Dominion, under Government control, in connection with lakes and navigable rivers, are as follows:

First. The through route between Montreal and the head of Lake Superior, 14 feet navigation:

Name of Waterway.	Canal.	River.	Remarks.

Second. Ottawa to Lake Champlain: Greenville, Carillon, St. Annes, Chambly, St. Ours Canals.

Third. Ottawa to Kingston (and Perth): Rideau River and Canal. (Connects with Perth by Tay Canal.)

Fourth. Lake Ontario at Trenton to Lake Huron at mouth of river Severn: Trent Canal (not completed).

Fifth. Ocean to the Bras d'Or Lakes: St. Peters Canal.

The Lake Borgue, Louisiana, Canal was formerly opened in August, 1901. It opens continuous water communication with lakes Maurepas, Ponchartrain, and Borgue, the Mississippi Sound, Mobile, and the Alabama and Warrior Rivers, and the entire Mississippi River system, and has an important bearing as a regulator of freight rates between these sections. The effects of the canals may be briefly summed up as: Shortening the distance between New Orleans and the Gulf points east of the Mississippi; bringing shipments from the Gulf coast direct to the levees at New Orleans; saving the transshipment of through freights, with a consequent reduction in freight rates; enabling sea-going vessels, drawing 10 to 12 feet of water, to come within 20 miles of New Orleans, saving all such craft the cost of towage and shortening, by 60 miles, direct water communication between New Orleans and the deep water of the Gulf. In addition to these effects may be enumerated the cheapening of coal for consumption at New Orleans. Coal has hitherto been floated down the rivers from Pittsburg, a distance of 2100 miles. The canal opens up the coal fields in the interior of Alabama for New Orleans consumption and reduces coal prices considerably, giving

an additional advantage to domestic industries and to steamers purchasing bunker coal. The canal is 7 miles long and from 150 to 200 feet wide. Bayou Dupree forms a portion of the canal. The lock chamber is 200 feet long, 50 feet wide and 25 feet deep, and connects the canal with the Mississippi River.

The Chicago Sanitary and Ship Canal connects Lake Michigan at Chicago with the Illinois River at Lockport, a distance of 34 miles. The canal was cut for the purpose of giving to the city of Chicago proper drainage facilities by reversing the movement of water, which formerly flowed into Lake Michigan through the Chicago River, and turning a current from Lake Michigan through the Chicago River to the Illinois River at Lockport, and thence down the Illinois River to the Mississippi. The minimum depth of the canal is 22 feet, its width at bottom 160 feet, and width at the top from 162 to 290 feet, according to the class of material through which it is cut. The work was begun September 8, 1892, and completed and the water turned into the channel January 2, 1900. The flow of water from Lake Michigan toward the gulf is now at the rate of 360,000 cubic feet per minute, and the channel is estimated to be capable of carrying nearly twice that amount. The total excavation in its construction included 28,500,000 cubic yards of glacial drift and 12,910,000 cubic yards of solid rock, an aggregate of 41,410,000 cubic yards. In addition to this the construction of a new channel for the Desplaines River became necessary in order to permit the canal to follow the bed of that river, and the material excavated in that work amounted to 2,068,659 cubic yards, making a grand total displacement in the work of 43,478,659 cubic yards of material which, according to a statement issued by the trustees of the sanitary district of Chicago, would, if deposited in Lake Michigan in 40 feet of water, form an island 1 mile square with its surface 12 feet above the water line.

All bridges along the canal are movable structures. The total cost of construction, including interest account, aggregated \$34,000,000, of which \$21,379,675 was for excavation and about \$3,000,000 for rights of way and \$4,000,000 for building railroad and highway bridges over the canal. The city and State authorities by whom the canal was constructed are now proposing to Congress to make this canal a commercial highway in case Congress will increase the depth of the Illinois and Mississippi Rivers to a depth of 14 feet, with locks for fleets of barges from Lockport, the terminus of the drainage canal, to St. Louis. This, it is argued, would give through water transportation from Lake Michigan to the Gulf by way of the drainage canal, the Illinois River, and the Mississippi River, and would enable the United States in case of war to quickly transport light-draft war vessels from the Gulf to the lakes. This work of deepening the Illinois River would also give through water connection from Rock Island, on the Upper Mississippi River, to Lake Michigan via the Illinois and Mississippi Canal, which extends from Rock Island, on the Mississippi River, to Hennepin, on the Illinois River. The estimate of the Chicago sanitary district trustees of the cost of deepening the Illinois and Mississippi Rivers from the terminus of the ship canal to St. Louis to a depth of 14 feet is \$25,000,000, including five locks and dams.

Proposed American Isthmian Canal.—The construction of a waterway to connect the Atlantic and Pacific across the American isthmus has been a subject of consideration for nearly 400 years. Vasco Nunez de Balboa, governor of a province in Darien, in 1513 crossed the isthmus and discovered the Pacific, and from that time forward efforts were almost constantly made to discover a water connection between the oceans at this point, which it was hoped nature had supplied. When this hope was abandoned the construction of an artificial water route was immediately proposed, and Charles V. is said to have directed, as early as 1520, that the Isthmus of Panama be surveyed with the purpose of selecting a route for the construction of an artificial waterway to connect the two oceans. Another decree was issued in 1534, authorizing a careful examination by experienced men for this purpose; but the governor having reported that such work was impracticable, and that no king, however powerful, was capable of forming a junction of the two seas, and the suggestion having been made that the opening of a canal through the isthmus would be "in opposition to the will of the Almighty, who had placed this barrier in the way of navigation between the two oceans," the project was temporarily abandoned. Further examinations were made in 1771 in the hope of finding a continuous water-

way, as statements had been made that a river had been found flowing from ocean to ocean, but an examination proved the inaccuracy of this statement. In 1779 a survey was made to determine the practicability of connecting the oceans by way of Lake Nicaragua, but the report was not encouraging. From that date forward, however, numerous examinations and surveys of the isthmus were made at various points, the latest being that of the American Commission appointed in 1899, and which has recently presented its full report to Congress. That report concludes as follows:

"The investigations of this Commission have shown that the selection of 'the most feasible and practicable route' for an isthmian canal must be made between the Nicaragua and Panama locations. Furthermore, the complete problem involves both the sea-level plan of canal and that with locks. The Panama route alone is feasible for a sea-level canal, although both are entirely practicable and feasible for a canal with locks. The time required to complete a sea-level canal on the Panama route, probably more than twice that needed to build a canal with locks, excludes it from favorable consideration, aside from other serious features of its construction. It is the conclusion of this Commission, therefore, that a plan of canal with locks should be adopted.

"A comparison of the principal physical features, both natural and artificial, of the two routes reveals some points of similarity. Both routes cross the continental divide less than ten miles from the Pacific Ocean, the Panama summit being about double the height of that in Nicaragua. For more than half its length the location of each route on the Atlantic side is governed by the course of a river, the flow from whose drainage basin is the only source of water supply for the proposed canal; and the summit levels, differing but about 20 feet in elevation, Panama being the lower, are formed by lakes, natural in the one case and artificial in the other, requiring costly dams and wasteways for their regulation and for the impounding of surplus waters to reduce the effect of floods and to meet operating demands during low-water seasons.

"The investigations made in connection with the regulation of Lake Nicaragua have demonstrated that that lake affords an inexhaustible water supply for the canal by that route. The initial proposition, on the other hand, for the Panama route is to form Lake Bohio so as to yield a water supply for a traffic of 10,000,000 tons, which can be supplemented when needed by an amount sufficient for more than four times that traffic, by means of the Alhajuela reservoir. For all practical purposes this may be considered an unlimited supply for the Panama route. So far as the practical operation of a ship canal is concerned, therefore, the water supply features on both lines are satisfactory.

"The difficulties disclosed and likely to be encountered in the construction of the dams are less at Conchuda on the Nicaragua line than at Bohio on the Panama route. Both dams, however, are practicable, but the cost of that at Bohio is one-half more than at Conchuda. A less expensive dam at Bohio has been proposed, but through a portion of its length it would be underlaid by a deposit of sand and gravel pervious to water. The seepage might not prove dangerous, but the security of the canal is directly dependent upon this dam, and the policy of this Commission has been to select the more perfect structure even at a somewhat greater cost. The wasteways at both locations present no serious difficulties. The advantages in the design and construction of the dams are in favor of the Nicaragua route.

"The system of regulation at Lake Bohio consists only of the discharge of water over the crest of a weir, as the lake level rises under the influence of floods in the Chagres River. The plan of regulating the level of Lake Nicaragua is less simple, though perfectly practicable. It involves the operation of movable gates at such times and to such extent as the rainfall on the lake basin may require. The experience and judgment of the operator are essential elements in the effective regulation of this lake. The regulation of Lake Bohio is automatic.

"The only means of transportation now found on the Nicaragua route are the narrow-gauge Silico Lake Railroad, about 6 miles in length, and the limited navigation of the San Juan River and the lake, but the Nicaraguan Government is now building a railroad along the beach from Greytown to Monkey Point, about 45 miles to the northward, where it proposes to establish a commercial port. By means of a pier, in the area protected by the point, goods and material for canal purposes can readily be landed and transported by rail to Greytown. Such piers are in constant use on our Pacific coast. This railroad and port would be of great value during the

period of preparation and harbor construction, and should materially shorten that period. A well-equipped railroad is in operation along the entire length of the Panama route, and existing conditions there afford immediate accommodation for a large force of laborers.

"The Nicaragua route has no natural harbor at either end. At both the Atlantic and Pacific termini, however, satisfactory harbors may be created by the removal of material at low-unit prices, and by the construction of protective works of well-established design. An excellent roadstead, protected by islands, already exist at Panama, and no work need be done there for either harbor construction or maintenance. At Colon, the Atlantic terminus of the Panama route, a serviceable harbor already exists. It has afforded harbor accommodations for many years, but it is open to northers, which a few times in each year are liable to damage ships or force them to put to sea. Considerable work must be done there to create a suitable harbor at the entrance of the canal, which can easily be entered, and will give complete protection to shipping lying within it. The completion of the harbors as planned for both routes would yield but little advantage to either, but the balance of advantages, including those of maintenance and operation, is probably in favor of the Panama route.

"The existence of a harbor at each terminus of the Panama route, and a line of railroad across the Isthmus, will make it practicable to commence work there, after the concessions are acquired, as soon as the necessary plant can be collected and put in place, and the working force organized. This period of preparation is estimated at one year. In Nicaragua this period is estimated at two years, so as to include also the construction of working harbors and terminal and railroad facilities.

"The work of excavation on the Nicaragua route is distributed; it is heaviest near Conchuda, at Tamborcito, and in the divide west of the lake. On the Panama route it is largely concentrated in the Culebra and Emperador cuts, which are practically one. As a rule distributed work affords a greater number of available points of attack, contributing to a quicker completion; but in either of these cases such difficulties as may exist can be successfully met with suitable organization and efficient appliances.

"The time required for constructing the Nicaragua Canal will depend largely on the promptness with which the requisite force of laborers can be brought to Nicaragua, housed and organized at the locations of heaviest work along the route. The cut through the divide west of the lake will probably require the longest time of any single feature of construction. It contains about 18,000,000 cubic yards of earth and rock excavation, or a little less than 10 per cent of the total material of all classes to be removed. With adequate force and plant this Commission estimates that it can be completed in four years. This indicates, under reasonable allowance for ordinary delays, that if force and plant enough were available to secure a practically concurrent execution of all portions of work on the route, the completion of the entire work might be expected within six years after its beginning, exclusive of the two years estimated for the period of preparation.

"The securing and organizing of the great force of laborers needed, largely foreigners, so as to adjust the execution of the various portions of the work to such a definite programme of close-fitting parts in a practically unpopulated tropical country, involves unusual difficulties and would prolong the time required for completion.

"The greatest single feature of work on the Panama route is the excavation in the Culebra section, amounting to about 48,000,000 cubic yards of hard clay, much of which is classed as soft rock, or nearly 45 per cent of all classes of material to be removed. It is estimated that this cut can be completed in eight years, with allowance for ordinary delays, but exclusive of a two-year period for preparation and for unforeseen delays, and that the remainder of the work can be finished within the same period. The great concentration of work on this route and its less amount will not require so great a force of laborers as on the Nicaragua route; hence the difficulties and delays involved in securing them will be correspondingly diminished.

"The total length of the Nicaragua route from sea to sea is 183.66 miles, while the total length of the Panama route is 49.09 miles. The length of standard canal section and in harbors and entrances is 73.78 miles for the Nicaragua route and 36.41 miles for the Panama route. The length of sailing line in Lake Nicaragua is 70.51 miles, while that in Lake Bohio is 12.68 miles. That portion of the Nicaragua route in the canalized San Juan is 30.37 miles.

"The preceding physical features of the two lines measure the magnitude

of the work to be done in the construction of waterways along the two routes. The estimated cost of constructing the canal on the Nicaragua route is \$45,630,704 more than that of completing the Panama Canal, omitting the cost of acquiring the latter property. This sum measures the difference in the magnitude of the obstacles to be overcome in the actual construction of the two canals and covers all physical considerations, such as the greater or less height of dams, the greater or less depth of cuts, the presence or absence of natural harbors, the presence or absence of a railroad, and the amount of work remaining to be done.

"The estimated annual cost of maintaining and operating the Nicaragua Canal is \$1,300,000 greater than the corresponding charges for the Panama Canal.

"The Panama route would be 134.57 miles shorter from sea to sea than the Nicaragua route. It would have less summit elevation, fewer locks, 1,568 degrees and 26.44 miles less curvature. The estimated time for a deep-draft vessel to pass through is about 12 hours for Panama and thirty-three hours for Nicaragua. These periods are practically the measure of the relative advantages of the two canals as waterways connecting the two oceans, but not entirely, because the risks to vessels and the dangers of delay are greater in a canal than in the open sea.

"Except for the items of risks and delays, the time required to pass through the canals need be taken into account only as an element in the time required by vessels to make their voyages between terminal ports. Compared on this basis, the Nicaragua route is the more advantageous for all transisthmian commerce except that originating or ending on the west coast of South America. For the commerce in which the United States is most interested, that between our Pacific ports and Atlantic ports, European and American, the Nicaragua route is shorter by about 1 day. The same advantage exists between our Atlantic ports and the Orient. For our Gulf ports the advantage of the Nicaragua route is nearly two days. For commerce between North Atlantic ports and the west coast of South America the Panama route is shorter by about two days. Between Gulf ports and the west coast of South America the saving is about one day.

"The Nicaragua route would be the more favorable one for sailing vessels because of the uncertain winds in the Bay of Panama. This is not, however, a material matter, as sailing ships are being rapidly displaced by steamships.

"A canal by the Panama route will be simply a means of communication between the two oceans. That route has been a highway of commerce for more than three hundred years, and a railroad has been in operation there for nearly fifty years, but this has effected industrial changes of but little consequence, and the natural features of the country through which the route passes are such that no considerable development is likely to occur as a result of the construction and operation of a canal.

"In addition to its use as a means of communication between the two oceans, a canal by the Nicaragua route would bring Nicaragua and a large portion of Costa Rica and other Central American States into close and easy communication with the United States and with Europe. The intimate business relations that would be established with the people of the United States during the period of construction by the expenditure of vast sums of money in these States and the use of American products and manufactures would be likely to continue after the completion of the work, to the benefit of our manufacturing, agricultural, and other interests.

"The Nicaragua route lies in a region of sparse population and not in a pathway of much trade or movement of people: conditions productive of much sickness do not exist. On the other hand, a considerable population has long existed on the Panama route, and it lies on a pathway of comparatively large trade, along which currents of moving people from infected places sometimes converge, thus creating conditions favorable to epidemics. Existing conditions indicate hygienic advantages for the Nicaragua route, although it is probable that no less effective sanitary measures must be taken during construction in the one case than in the other."

The relative estimated cost of the Nicaragua and Panama canals is as follows: Nicaragua \$189,864,962; completing the Panama canal \$144,233,358 + \$40,000,000 for acquiring the rights and property of the New Panama Canal Co., making a total of \$184,233,358. [Actual cost will be double.]

Estimates of annual cost of maintenance are: Nicaragua canal, \$3,300,000; Panama canal \$2,000,000.

a Via Honolulu adds 374 miles for Nicaragua and 252 for Panama.

b Omitting Tahiti reduces voyage from Brito by 52 miles.

c Voyage from Brito to Sydney by Wellington is 233 miles less than by way of Tahiti; from Panama it is 405 miles less.

d Voyage from Brito to Wellington direct is 185 miles shorter than via Tahiti, and from Panama it is 358 miles shorter.

The Harlem River Ship Canal, connecting the Hudson River and Long Island Sound, by way of Spuyten Duyvil Creek and Harlem River, was opened for traffic on June 17, 1895, and cost about \$2,700,000.

Cost of Maintenance and Operation of Canals.—In order to form an estimate of the cost of maintaining and operating the Isthmian Canal, the Isthmian Canal Commission obtained data bearing on this point from the Suez, Manchester, Kiel, and St. Marys Falls canals, as follows:

There are no locks on the Suez Canal, but the channel is through drifting sand for a great part of its length. The entrance to the harbor of Port Said on the Mediterranean intercepts the drift of sand discharged from the Nile and carried along the coast by the easterly current. The maintenance of the Suez Canal therefore requires a large amount of dredging and consists mainly of this class of work. The operating expenses are also large, the great traffic involving heavy costs for pilotage. The general expenses for administration have necessarily been greater for the Suez Canal than for the Kiel or Manchester Canals, on account of the distance of the work from the point of central control, a disadvantage which would also attend the operation of the Isthmian Canal. The annual cost of maintenance and operation of the Suez Canal is about \$1,300,000, or about \$13,000 per mile.

The annual cost of maintenance and operation of the Kiel Canal is \$8,600 per mile. The cost of maintenance only of the Manchester Canal is \$9,500 per mile. These canals have locks and other mechanical structures, and therefore might be expected to have a higher cost of maintenance than the Suez Canal, which has none, but this appears to be more than offset by reduced cost of maintaining the prism and more economical central control. The traffic being light on these canals, the cost of pilotage and port service is small. The mechanical structures are now nearly new, and will soon require larger annual outlays for maintenance, while, with the increase of traffic, operating expenses will become larger.

The St. Marys Falls Canal, when compared with those just mentioned, is remarkable by reason of its short length, large proportion of mechanical structures, and immense traffic. Its length is about $1\frac{1}{2}$ miles. Its annual traffic, limited by the severity of the winter to a period of about eight months, is nearly three times that of the Suez Canal, eight times that of the Kiel Canal, and ten times that of the Manchester Canal. Both maintenance and operating expenses are therefore very large, amounting to from \$70,000 to \$90,000 per year, or \$46,000 to \$60,000 per mile. The annual cost per mile of maintenance and operation, however, for comparison with other canals, should be determined by considering the $18\frac{1}{2}$ miles of dredged channel ways in St. Marys River as part of the canal. Then for the 20 miles of canal and canalized river the expenses per mile would be from \$3,000 to \$5,000 annually. Tolls were collected by the State from 1855 to 1881. Since its ownership by the government no tolls have been charged.

The Principal Commercial Canals of the U. S., showing cost of construction (which includes cost of improvements), date of completion, length, number of locks, and *navigable* depth, are given in Table 3, on following page, which is reproduced, by permission, from the New York World Almanac.

Albemarle and Chesapeake.	1860	44	1	7½	Norfolk, Va., to Currutuck Sound, N. C

68.—WATER POWER.

Definitions and Formulas.—Power is the *rate* of work (see page 391); and Water Power is the rate of work available from stored or flowing water, through the agency of gravity. The unit of mechanical power is the Horse-Power (*H. P.*), equivalent to the energy expended in raising 550 lbs. one ft. high in one second, or to the energy of 550 lbs. falling one ft. in one second. Hence, the theoretic horse-power of a stream is—

$$H. P. = \frac{62.37 Q h}{550} = 0.1134 Q h \dots\dots\dots (1)$$

where 62.37 = weight of a cu. ft. of water at 60°F., in lbs.;

Q = discharge of stream, in cu. ft. per sec.;

h = fall of water, or available head, in ft.

Whence
$$Q = \frac{8.82 \times H. P.}{h} \dots\dots\dots (2)$$

and
$$h = \frac{8.82 \times H. P.}{Q} \dots\dots\dots (3)$$

"Horse-Power Hours" is a term used to denote a certain *amount* of work or energy, and not the rate of work. It is the maintenance of one horse-power for one hour, or of ten horse-power for six minutes, etc.; and may be applied to definite quantities or volumes of stored or running water. Thus,

$$\text{No. of } H.-P. \text{ hours} = \frac{62.37 V h}{550 \times 3600} = 0.000315 V h \dots\dots\dots (4)$$

where V = volume of stored water, in cu. ft.;

3600 = No. of seconds in one hour.

Whence
$$V = \frac{31746 \times \text{No. of } H.-P. \text{ hours}}{h} \dots\dots\dots (5)$$

and
$$h = \frac{31746 \times \text{No. of } H.-P. \text{ hours}}{V} \dots\dots\dots (6)$$

At the Prime Motor the available horse-power is always less than the theoretic horse-power, the decrease being due to loss of head, leakage or waste, evaporation, etc., depending upon the character of conduit or canal. Equation (1) will give the available horse-power at the prime motor if—

Q = actual discharge, in cu. ft. per sec., at prime motor;

h = effective head, in ft., at prime motor.

Economic Design of Penstock.—For a high-pressure water-power pipe, the volume of discharge being assumed fixed or constant, the following economic relation holds true:

"That pipe fulfills the requirements of greatest economy wherein the value of the energy annually lost in frictional resistance equals four-tenths (0.4) of the annual cost of the pipe line."^{*}

Thus, if L = value of energy annually lost in frictional resistance,

and C = annual cost of pipe line;

then $L = 0.4 C$, for economic design of pipe.

^{*} Mr. A. L. Adams, in Trans. Am. Soc. C. E., Vol. LIX, page 177.

1.—NUMBER OF HORSE-POWER, EQUIVALENT TO FLOW OF 1 CU. FT.
PER SEC. UNDER VARIOUS EFFECTIVE HEADS. (EQUA. 1.)
(To find the total H. P., mult. values in Table by No. of cu. ft. per sec.)
[Horse-Power per Cu. Ft. per Sec. of Flow.]

* Effective head and actual horse power are proportional; hence the decimal point may be moved in each, a corresponding number of places to right or left.

Ex.—The equivalent to a flow of 1 cu. ft. per sec. under a head of 14 ft. is 1.6876 H. P.; under a 140-ft. head, 15.876 H. P.; under a 1400-ft. head, 158.76 H. P.

2.—NUMBER OF HORSE-POWER HOURS, EQUIVALENT TO STORAGE OF 1 000 000 CU. FT. UNDER VARIOUS EFFECTIVE HEADS. (EQUA. 4.)

(To find total H.-P. H., mult. values in Table by No. of millions of cu. ft. stored.)

[Horse-Power Hours per each million cu. ft.]

* Effective head and actual horse-power hours are proportional; hence the decimal point may be moved in each, a corresponding number of places to right or left.

Ex.—The equivalent to a storage of 1 000 000 cu. ft. with a head of 14 ft. is 441 H.-P. H.; with a 140-ft. head, 4410 H.-P. H.; with a 1400-ft. head, 44100 H.-P. H.

3.—NUMBER OF HORSE-POWER HOURS, EQUIVALENT TO STORAGE OF 1 ACRE-FOOT. UNDER VARIOUS EFFECTIVE HEADS. (EQUA. 4.)

find the total H.-P. H., mult. values in Table by No. of acre-feet stored.)

Note.—1 acre-foot = 43560 cubic feet.

[Horse-Power Hours per each acre-foot.]

* Effective head and actual horse-power hours are proportional; hence a decimal point may be moved in each, a corresponding number of places right or left.

Ex.—The equivalent to a storage of 1 acre-foot with a head of 14 ft. is 210 H.-P. H.; with a 140-ft. head, 192.10 H.-P. H.; with a 1400-ft. head, 21.0 H.-P. H.

Water Motors.—The energy of flowing water, by virtue of its velocity, weight and pressure, all acting together to a greater or less extent, may be transmitted to mechanical motors and transformed into various kinds of forms of energy. The principal types of water motors comprise many of the various forms of wheels, among which are the following:*

The Current Wheel is the simplest form. It consists essentially of a paddle wheel with blades, somewhat similar to the side wheel of a steamboat, and is mounted on a horizontal shaft, supported over the current of water at the bank of the stream, and adjustable to height. The principal use of the current wheel in the West is for raising water for domestic supply and irrigation purposes. Attached to, or near, the periphery of the wheel are open metal buckets which scoop up the water from the stream and then deliver it into a flume whence it is conveyed into reservoirs, or directly on the land. A small wheel will irrigate several acres. Prof F. H. King, in describing the wheels used in Bavaria on the River Regnitz, a branch of the Main, where he counted no less than 20 in a distance of $1\frac{1}{2}$ to $1\frac{1}{4}$ miles, says:†

These wheels have a diameter of 16 ft. and carry upon one or both sides a row of 24 churn-like buckets each lifting out of the stream, and to a height of 12 ft., not less than 3 galls. of water, from which it is conveyed to the bank through a conduit hewn from a log. The wheel under consideration was making at the time of the writer's visit four revolutions each minute, so that the water lifted was not less than 288 gallons per minute, and probably exceeded 300 gallons. Another wheel with a row of buckets on each side was making three revolutions and discharging not less than 450 gallons per minute. The first of these wheels was pumping water at a rate sufficient to irrigate, to a depth of 4 inches every 10 days, 38 acres, and the second 60 acres.

The ordinary current wheel is sometimes called an "undershot wheel," although this is a misnomer.

The Undershot Wheel of approved design has curved blades or buckets. The current is accelerated by the construction of a flume with a decided grade and perhaps also by inserting a headgate giving increased head. The principle is somewhat similar to that of the current wheel, the water flowing beneath it. The efficiency is very low, rarely exceeding 40 per cent.

The Breast Wheel has pronounced buckets and acts as a dam, backing the water up nearly to its top so that all the buckets on the up-stream side are filled with water. Being thus continually unbalanced it is revolved. The efficiency ranges at about 60 to 65 per cent.

The Overshot Wheel has a greater efficiency than either of those previously described, reaching in some cases 75 per cent. The water is conveyed by flume over the top of the wheel, filling the buckets on the down-stream side, producing an unbalanced force on the horizontal shaft, which is connected up with the working machinery.

Impulse Wheels and *Turbine Wheels* are the most common forms of water motors, and are discussed below.

Impulse Water Wheels.—This type is the most efficient and economical of any of the pure types of water wheel on the market. It also compares favorably with turbines for moderate heads of water, and surpasses them for high heads. In principle, the impulse water wheel consists essentially of a wheel mounted on a horizontal shaft. Attached to the circumference of the wheel are numerous double-cup-shaped buckets into which one or more tangential jets of water are played from nozzles. The greatest amount of energy of the jet has been imparted to the wheel when the velocity of the jet has been totally destroyed, and this is accomplished by the peculiar shape of the buckets which split the jet in the middle and reverse either half in direction by 180° . When the water simply falls from the buckets, by the action of gravity, the wheel is working with the greatest jet efficiency.

Fig. 1 illustrates the Pelton water wheel with needle and single deflecting nozzle, for economic regulation. The needle nozzle consists of a tapered needle which may be operated so as change the discharge area of the nozzle.

* The hydraulic ram and the hydraulic pressure engine are not included in this discussion.

† See Farmer's Bulletin No. 46, U. S. Dept. of Agriculture.

deflecting nozzle is simply a cast-iron nozzle provided with a ball and jet joint. It can be arranged automatically to raise and throw the jet the buckets or to lower and throw it off. Intermediate positions are obtained by change of "load."

Fig. 1.

The number of nozzles (one, two, or more) which it is advisable to use on a wheel depends upon the head of water and also upon the amount of power required. As a general rule it may be stated that the power developed is proportional to the amount of water or number of nozzles used, the head of water and size of nozzles remaining constant. Double nozzles are often used on small wheels which are called for by certain speed requirements and where the single nozzle would not give the required power. The quintex nozzle wheel is specially designed for very low head. (See plate 5, page 1342.)

4.—SINGLE NOZZLE PELTON WATER WHEEL DATA.

(Suitable for high heads.)

Note.—Compare with Table 5 for low heads, making due allowance for 5 nozzles in that table.

The Calculations for Power in these Tables are based upon the application of one stream to the wheel and on effective heads. In using these tables liberal allowance should be made to cover the friction loss in pipe, elbows, gates, etc. The smaller figures under those denoting the various heads give the equivalent pressure in pounds per square inch, and spouting velocity of water in feet per minute. The water measurement is also based on the flow per minute.

Turbine Water Wheels.—Turbines differ from the wheels, described above, in this respect: That in the case of the wheels the water acts only upon a portion of their circumference at any one instant, while with the turbines the water acts symmetrically and uniformly upon the moving parts. Turbines consist essentially of two main parts, namely, (1) the wheel (runner) with vanes arranged around the circumference, and revolving on a vertical or horizontal shaft; and (2) the casing, provided with fixed guide vanes to give direction to the flow of water before it reaches the vanes of the wheel. Turbines are sometimes classified as "radial," "axial" and "combined or mixed;" and again, as *reaction-* and *impulse* turbines. In a radial turbine the water may flow from the circumference inward to the center, or the reverse; in an axial turbine, from the top downward or from the bottom upward; and in a combined turbine, inward and down or up, or outward and down or up. Turbines are most commonly mounted on vertical shafts with water flowing simply inward, outward or downward. The difference in principle between a reaction turbine and an impulse turbine is this: A reaction turbine is driven by the dynamic force of the flowing water augmented by static pressure to a greater or less extent; when there is no static pressure it becomes an impulse turbine. Standard makes of turbines will give an efficiency of from 65 to 85 per cent. An efficiency of 80 per cent can be counted upon for the best makes.

Nomenclature of Terms.—Mr. John W. Thurso suggests the following, for uniformity.

For "water wheel" say "turbine" whenever a turbine is meant.

For "Jonval" turbine say "reaction" turbine. For Girard, Pelton, impulse or free deviation turbine say "action" turbine. For Fourneyron or Boyden turbine say "radial outward flow reaction" turbine, or else simply "outflow reaction" turbine.

For Francis turbine say "radial inward flow reaction" turbine, or simply "inflow reaction" turbine, as this type is usually understood by the name Francis turbine. While it is not likely that the term Francis turbine will go out of use, the term "inflow reaction" turbine should always be used where an exact expression is of importance, as in contracts, for the reason that Mr. Francis also designed outflow reaction turbines.

For "parallel flow" turbine say "axial" flow turbine, or axial turbine. For "segmental feed" turbine, say "partial feed" turbine, or "partial" turbine.

For one, two, three, four five or six turbines on one shaft say single, double, triple, quadruple, quintuple or sextuple turbine.

For "draft chest" or "camelback" say "draft-tee." For "butterfly gate" say "wing-gate." For "feeder-pipe" or "water feeder" say "penstock."

For open flume say "turbine-chamber" whenever a turbine chamber is meant, leaving the term "flume" to mean a water conductor only, built of wood, steel or masonry, and carrying water not under pressure.

For the distance to which a vertical draft tube reaches below the surface of the tailwater, say dip of draft tube.

For speed of water in the cylindrical part of the penstock say "penstock speed." For speed of water, while leaving or quitting lower end of draft tube, say "draft tube speed."

For the part of the head that is above the turbine say "pressure head." For the part of the head that is utilized by means of a draft tube, say "draft head."

The water available under the head utilized should be called "power water," corresponding in meaning to the term live steam. The water having descended either through the turbines or over the falls, should be called "tail-water," corresponding in meaning to the term exhaust steam.

The terms horizontal or vertical turbine should always mean a turbine on a horizontal or vertical shaft, and never one revolving in a horizontal or vertical plane, as it is now sometimes understood.

The area left open or clear by the regulating gate or gates for the passage of the water should be called "gate opening." At present the term "gate opening" or "gate" is nearly always used to mean the amount of water flowing through the gate opening, but this amount should be designated by discharge; for example, instead of saying: "This turbine, with five-eighths gate opening, gave an efficiency," etc., should be said: "This turbine, with five-eighths discharge, gave an efficiency," etc., whenever the discharge is meant.

The motor furnishing the power for actuating the regulating gates of a turbine, and usually controlled by a speed governor, should be called a relay. In Europe the term servomotor is used for such auxiliary machines.

Losses of Energy in Turbines.—These losses may be segregated as follows:

- (1) The hydraulic loss in the casing, from the penstock flange to the entrance to the guides (guide vanes); this is dependent to a large extent on the velocity of flow in the casing, it being remembered that for a "given velocity" the percentage of loss decreases with the increase of head.
- (2) The hydraulic loss in the guides and runners; this is affected by the type of runner (wheel) and the design of the guides, but the percentage of hydraulic loss remains practically constant for any one type if the speed is allowed to vary as $\sqrt{h}$, in which h = the head, in feet.
- (3) The hydraulic loss due to the leakage around the runner; this, as well as the discharge, varies as the $\sqrt{h}$, hence the ratio of leakage to discharge remains constant.
- (4) The hydraulic loss in the draft-tube.
- (5) The mechanical loss due to the friction of the revolving parts; this increases with the head, h , but the percentage of mechanical loss decreases with the head.

Efficiencies of Turbines.—The term "efficiency" is often used loosely, and it is very important that in turbine tests, and in specifications and

contracts, the specific kind of efficiency which is meant should be stated. There are four kinds of efficiencies which may be employed, namely:

- (a) The hydraulic efficiency, embracing losses (1), (2) and (3), above.
- (b) The mechanical efficiency, embracing loss (5), above.
- (c) The efficiency of the turbine as a whole, being the product of the hydraulic and mechanical efficiencies, (a) and (b).
- (d) The efficiency of the plant as a whole, comprising the turbine efficiency (c) and embracing the draft-tube loss (4) and the penstock loss.

Theoretic Horse-Power of Turbines.—The theoretic horse-power of a turbine varies as $h^{1.5}$, in which h = the head of water in feet. This is true since the horse-power is proportional to the pressure of the water (which in turn varies with h , being equal to about $62.37ah$, see Table 1, preceding), and to the velocity of flow per second (which in turn varies with $\sqrt{h}$, being equal to $v = 8.02\sqrt{h}$). Thus,

$$\text{Theoretic H. P.} = \frac{62.37ah \times 8.02\sqrt{h}}{550} = 0.909468 ah^{1.5} \dots\dots\dots (7)$$

In which a = area of discharge in square feet;
 h = head in feet.

Formula (1), preceding, is the same as formula (7), but expressed in terms of discharge Q instead of area a .

When the efficiency of the turbine (or plant) has been determined, the actual H. P. is obtained by multiplying the values of equations (1) or (7) by said efficiency, expressed in per cent.

The Transmission of Power from water motors to machinery is through the main shaft, and may be by belt, by gearing or by coupling. If the power is for electric transmission it is customary to connect the main shaft of the wheel or turbine directly with the electric dynamo or generator. Hence the term "direct-connected generator."

69.—STEAM AND GAS POWER.

A.—HEAT.

Matter and Energy.—In the light of modern science, all natural phenomena are due to matter and energy.

Matter may be defined as anything capable of entering into chemical combination, and hence is made up of the chemical elements, of which the total known number, now about 90, may vary with future discoveries. By the Law of the Conservation of Matter, as deduced from chemistry, we learn that matter is indestructible: it may appear in various forms, yet the constituent elements are never actually lost or destroyed. Matter may exist in a solid, liquid, gaseous, or ethereal state.

Energy is matter in motion, and is measured by the formula,

$$\text{Energy} = \frac{1}{2} \text{mass} \times (\text{velocity})^2; \text{ or } E = \frac{1}{2} M V^2 \dots \dots \dots (1)$$

in which mass M = force F $\times$ acceleration a ,

= weight W $\div$ gravity acceleration g .

The Law of the Conservation of Energy, proven by various experiments, teaches us that energy is indestructible: it can appear and disappear in various forms, yet none of it is actually lost or destroyed.

From the foregoing laws of the conservation of matter and energy, and from equation (1), we deduce the following: That the summation of each individual, infinitesimal sub-atom of matter in the universe, multiplied by the square of its velocity, at any single instant, is equal to twice the total energy in the universe and is a constant. Or, applied to any independent system protected from outside influences, the same statement holds true; hence in any such system, we have,

$$\frac{1}{2} M V^2 = \text{a constant} \dots \dots \dots (2)$$

without regard to any change in *form* of the matter or its motion.

Kinds of Energy.—There are two kinds of energy generally referred to, namely, Kinetic or *actual* ("moving") energy, and Potential or *stored* (static) energy. Strictly speaking, potential energy is simply a term used to express the amount of kinetic energy which would be expended by a mass in changing itself from one state, condition or position which it has assumed, to another state, condition or position which is *predetermined*. The energy expended may be in one or more forms.

Forms of Energy.—There are four principal forms or outward manifestations of energy:

Examples.

Mass (?) or	Potential:	A raised weight.
Mechanical.	Kinetic:	the falling of a raised weight.
Molecular (?)	Potential:	the latent heat of liquefaction.
or Thermal.	Kinetic:	the release of latent heat.
Atomic (?) or	Potential:	the energy stored in dynamite.
Chemical.	Kinetic:	the discharge of dynamite.
Ethereal (?) or	Potential:	the electric charge in a leyden jar.
Electrical.	Kinetic:	the discharge of a leyden jar.

Other manifestations of energy are light, sound, magnetism, etc.

Transformation of Energy.—Energy which is manifest in one form may appear in another forms:

Examples.

Mechanical to	Thermal:	(1) Heat resulting from impact of a projectile
"	Chemical:	(2) [No direct transformation wholly kinetic?]
"	Electrical:	(3) Electric current generated from a dynamo

Thermal to	Chemical:	(4) Chemical building up of plant life by heat.
"	Electrical:	(5) Current generated by heating a thermo-electric pile.
"	Mechanical:	(6) The mechanical work of a steam engine.
Chemical to	Electrical:	(7) Current generated from a voltaic battery.
"	Mechanical:	(8) Energy of all animal and vegetable life.
"	Thermal:	(9) Heat from oxidation, as combustion of fuel.
Electrical to	Mechanical:	(10) Energy of an electric motor or fan.
"	Thermal:	(11) Heat evolved by current through non-conductor.
"	Chemical:	(12) Electrolytic action, as electroplating, etc.

Thermal Energy.—Heat and its effects may be considered as related to molecular action; and the transference of heat, simply as the transference of molecular action from one body to another, or from one medium to another.

First Law of Thermodynamics: Heat and mechanical energy are mutually convertible; and heat requires for its production, and produces by its disappearance, a certain definite number of *units of work* for each thermal unit.

Thermal Units.—There are three units as follows:

The *British* unit of heat or British thermal unit (B. T. U.) is equivalent to 778 foot-pounds of work, and may be defined as the quantity of heat required to raise the temperature of one pound of pure water 1° Fahrenheit, at or near its maximum density at 39.1° F. (most authors); or at the more prevailing temperature of 62° F. (Professor Peabody).

The *French* thermal unit or calorie (Cal.) is equivalent to 426.84 meter-kilograms of work, and may be defined as the quantity of heat required to raise the temperature of one kilogram of water 1° centigrade, at about 4° C. (39.1° F.).

The *British-French* unit of heat or "pound-calorie" (Lb.-Cal.) is equivalent to 1400.4 foot-pounds of work, and may be defined as the quantity of heat required to raise the temperature of one pound of water 1° C., at about 4° C.

Mechanical Equivalent of Heat, J .—One Joule* = J = 778 ft.-lbs. = 1 British thermal unit (B. T. U.), is generally used in the United States as the mechanical equivalent of heat (see above). Hence, J = 1 B. T. U. = 778 ft.-lbs. = 1.41⁴⁵ horse-power seconds = 0.023⁵⁷ h.-p. minute = 0.00039²⁹ h.-p. hour; and $\frac{1}{J}$ = 1 ft.-lb. = 0.001285 B. T. U. One horse-power hour = 1,980,000 ft.-lbs. = 2545 heat units. One horse-power = 2545 heat units per hour = 25,450 heat units per day of ten hours.

Tables 1 and 2, following, will be found useful in the conversion of mechanical and thermal power and work.

* Joule's original experiments gave J = 772 ft.-lbs.

35.712	9.	19.8414	27783.	3841.56
39.68	10.	22.046	30870.	4268.40

Ex.—9 B. T. U. = 2.268 Cal. = 5 Lb.-Cal. = 7002 ft.-lbs. = 968.13 meter-kilograms.

Caution.—In the above Table it is to be noted that the equivalents are for the same amount of work in each case; thus, 1 B. T. U. and 0.252 Calorie and 0.5556 Lb.-Cal. are each equal to 778 ft.-lbs. of work. But using compound units we have:

1 B. T. U. per pound = $\frac{1}{2}$ Cal. per kilogram = $\frac{1}{2}$ Lb.-Cal. per pound.

1.8 B. T. U. per pound = 1 Cal. per kilogram = 1 Lb.-Cal. per pound.

	549720.	7128000.	42768x10 ⁴	12960.	216.	9.

Examples in the Use of Table 2, preceding.

Part 1.—1 000 000 ft.-lbs. per day is at the rate of 694 44 ft.-lbs. per min., and equivalent to 53.556 heat units per hour. 53.556 heat units represent an amount of work equal to 1.2626 horse-power min., or .021 h.-p hour, or .000877 h.-p. day.

Part 2.—5 000 000 ft.-lbs. per hour = 6427 heat units per hour. 5 000 000 ft.-lbs., or 6427 heat units, are equal to 2.5252 horse-power hours, or 1 horse-power for 2.5252 hours, or 2.5252 horse-power for 1 hour.

Part 3.—33 000 ft.-lbs. per min. = $2313.6 + 231.36 = 2545$ heat units per hour.

Part 4.—One heat unit for any time T is equal to 778 ft.-lbs. in time T ; hence Columns 1 and 3 may be used independently of time, throughout the Table, to give Equivalent Work in Ft.-Lbs. and Heat Units.

Part 5.—60 horse-power min. = 2545 heat units.

Part 6.—357 horse-power hours = $763500 + 127250 + 17815 = 908565$ heat units, and equivalent to 706 860 000 ($= 70686 \times 10^4$) ft.-lbs. (per hour for 1 hour.)

Part 7.—Six horse-power days = 366480 heat units; and 366480 heat units per hour represent work at the rate of 6 842 880 000 ft.-lbs. per day.

B.—FUEL.

Heating Power of Fuels.—The amount of heat energy, in *B. T. U.*, contained in coal, wood and other fuels may be determined by three methods: (a) by chemical analysis; (b) by burning the fuel in a calorimeter; (c) by practical test in connection with a steam boiler.

(a) *Chemical Analysis.*—There are two kinds of analysis of coal (or fuel), namely, "proximate analysis" and "ultimate analysis."

Proximate Analysis separates the coal into moisture, volatile matter, fixed carbon, and ash. In making this analysis a pulverized sample is weighed carefully and then heated to a temperature not to exceed 280° F. When, after repeated weighings, it ceases to lose more weight, the loss in weight by this heating is recorded as "moisture." The heating is then continued in a crucible with a lid cover, and after the temperature is raised gradually to a red heat and continued for a few minutes until gas ceases to be driven off, the crucible is cooled in a dessicator, to prevent absorption of moisture from the air, and weighed, the loss in weight by this heating being recorded as "volatile matter." The heating is then continued and the crucible raised to a white heat, the lid being partly open to admit air to burn the coal, and when the carbon is burned away, leaving nothing but the ash, the latter is weighed when cooled and the loss in weight by this heating is recorded as "fixed carbon." The weight of the ash is of course recorded as "ash." If the weighings are recorded in percentages the sum of the four constituent parts will add up to 100 per cent. Sometimes "sulphur" is included in the proximate analysis, either as part of the 100 per cent above mentioned or separately, the percentage of sulphur being determined by separate analysis, and 40 to 50% assumed to have escaped with the volatile matter and 60 to 50% with the fixed carbon.

The proximate analysis, above, indicates the character of the coal. Omitting the moisture and the ash, and letting the sum of the "volatile matter" and "fixed carbon" equal 100 per cent of the "combustible," we have the following classification:

3.—COALS CLASSIFIED BY RELATIVE PERCENTAGES OF CARBON AND VOLATILES.

Kind of Coal.	Per cent Fixed Carbon.	Per cent. Volatile Matter.	Heating Value. B. T. U. per Lb. Coal.	Relative Combustible Value.
Anthracite.....	100 to 92	0 to 8	14600 to 14800	93
Semi-Anthracite.....	92 to 87	8 to 13	14700 to 15000	94
Semi-Bituminous.....	87 to 75	13 to 25	15500 to 16000	100
Bituminous, Eastern.....	75 to 60	25 to 40	14800 to 15300	95
Bituminous, Western....	65 to 50	35 to 50	13500 to 14800	90
Lignite.....	under 50	over 50	11000 to 13500	77

4.—PROXIMATE ANALYSIS AND HEATING VALUES OF U. S. COALS.

Note.—See Table 5 for Ultimate Analyses of Fuels.

Kind of Coal.	Moisture.	Volatile Matter.	Fixed Carbon.	Ash.	Sulphur.	Heating Value per lb. Coal, Heat Units.	Volatile Matter per cent. of combustible.	Heating Value per lb. Combustible, Heat Units.	Theoretical Evaporation lbs. Water from and at 212° per lb. Combustible.

Green wood contains from 25 to 50 per cent moisture. Air-dried wood contains from 10 to 20 per cent moisture—usually 12 to 15 per cent.

Calculations of the Heat of Combustion of a fuel, based on the ultimate analysis, are usually performed by means of Dulong's formula, or by means of other formulas which resemble, or are more or less modifications of, Dulong's formula. Thus,

The total heat units (B. T. U.) per lb. of coal—

$$= 14650 C + 62100 (H - \frac{1}{8} O) \dots\dots (\text{Dulong}) \dots\dots (1)$$

$$= 14650 C + 62100 H - 5400 (O + N) (\text{Mahler}) \dots\dots (2)$$

In which C , H , O and N represent the relative parts of carbon, hydrogen, oxygen and nitrogen in the coal.

Example.—The ultimate analysis of a certain coal gave, in parts (percentages expressed in parts of a unit), carbon (C) = 0.8566, hydrogen (H) = 0.0278, nitrogen (N) = 0.0077, oxygen (O) = 0.0287, ash = 0.0733, volatile sulphur = 0.0059. How many heat units would one pound of this coal be expected to supply, or in other words, what is the total heat of combustion?

Solution.—From Dulong's formula, total heat = $14650 \times 0.8566 + 62100 (0.0278 - \frac{1}{8} \times 0.0287) = 14052$ B. T. U.; and from Mahler's formula, total heat = 14079 B. T. U.

Mr. Henry J. Williams* gives the following values for heat of combustion, as calculated by Dulong's formula:—Anthracites: Lehigh, 13963 B. T. U., Lykens Valley, 13954; Drifton, Pa., 14171. Semi-bituminous: Poca-hontas, 14805; Georges Creek, 14484; Clearfield, Pa., 14448; New River, W. Va., 14607. Bituminous: Connellsville (coking), 14043; Big Muddy, Cartersville, Ill., 12561; Dominion, Cape Breton, 13755; Pittsburg (steaming), 13719. But compare these heating values with those in Table 4, preceding.

(b) **Calorimeter.**—The "bomb calorimeter" is an instrument used to determine the actual heating value of coal. Mahler's instrument consists of a strong steel vessel immersed in water. One gram of the coal is placed in a platinum vessel within the bomb, oxygen gas is introduced, and the coal

* See page 41, *Steam Boilers*, by Peabody and Miller; John Wiley & Sons, New York.

ignited by an electric spark. The resultant heat of combustion is radiated into the surrounding water and is measured by the rise in temperature of the water, making the necessary corrections for absorption of heat by the instrument itself.

This method agrees usually within 2 per cent of the calculations from chemical analysis, when the tests are carefully made.

(c) *Practical (Boiler) Test.*—The following Table gives the summary of nine tests made on one 250 H. P. Cahall boiler at factory of the Armstrong Cork Co., Pittsburg, Pa., 1896:

6.—AVERAGE OF NINE BOILER TESTS—COAL AS FUEL.

C.—STEAM.

General Discussion.—If one pound of ice at absolute zero ($= -273.7^{\circ}\text{C}$ $= -460.66^{\circ}\text{F.}$) is gradually heated, its temperature will rise about directly in proportion to the amount of heat it receives (say approx. $^{\circ}\text{C.}$ per each Calorie, or 1°F. for each B. T. U.) until it reaches the melting point or fusion point ($= 0^{\circ}\text{C.} = +32^{\circ}\text{F.}$); then its temperature will remain constant during melting or until it has received 143 additional B. T. U., making a total of about $460.66 + 32 + 143 = 635.66$ B. T. U. to change one pound of ice at absolute zero into one pound of water at the temperature of freezing.*

The 143 B. T. U. required to change one pound of ice at $+32^{\circ}\text{F.}$ into one pound of water at 32°F. is called the latent heat of fusion of ice, and represents the work required to change the molecular condition of ice to the molecular condition of water, since there is no rise in temperature. Conversely, one pound of water at 32°F. will give out 143 B. T. U. in changing to ice at 32°F.

If one pound of water is gradually heated in an open vessel, under an atmospheric pressure of 14.7 pounds per square inch, from freezing point at 32°F. up to the boiling point at 212°F. , its temperature will rise almost directly in proportion to the amount of heat received, i. e., 1°F. for each B. T. U., or a total of 180 B. T. U.; then its temperature will remain constant during the process of boiling away, called vaporization. But if the atmospheric pressure on the surface of the water had been increased, its boiling point would have been raised. This is shown clearly in the first two columns of Tables 7 and 8, following. Thus, from Table 8, an absolute pressure of 90 pounds per square inch would raise the boiling point temperature to 320°F. and it would remain at that temperature until completely vaporized. In this case, the pound of water would become the receptacle of about $320 - 212 = 108$ B. T. U. more than it could receive under ordinary atmospheric pressure. It is thus seen that the temperature under which steam is generated, depends upon the pressure of the liquid.

Starting with one pound of water at 32°F. , and heating it, we find from Column 3, Tables 7 and 8, the number of heat units received at the various boiling-point temperatures, under corresponding pressures; and if the heating is continued at the boiling point, Column 5 shows the number of heat units required to convert the water into steam at the same temperature, called the heat of vaporization; and Column 4 shows the total heat in B. T. U., of the steam above that which the water contained at 32°F. Thus, for a temperature of 320°F. , the total heat $= 1179.5 - 290.0 + 889.5 =$ heat of the liquid + heat of vaporization.

It is to be remembered that the heat of vaporization, or latent heat of vaporization, represents the number of heat units consumed in changing one pound of water into steam at the same temperature. Now as the temperature is not raised, it is evident that some other work is being performed. In fact, the latent heat is converted into the work of separating the molecules of the water: (1) against molecular attraction, and (2) against external resistance or pressure. The 1st is called the heat equivalent of internal work (Table 7, Column 6), and the 2nd is called the heat equivalent of external work (Column 7). It is evident, then, that the value in Column 5 of Table 7, for any definite temperature or pressure, is equal to the sum of the corresponding values in Columns 6 and 7.

Steam generated in a closed vessel is necessarily in contact with the water and must have the same temperature and pressure as the water. In this condition it is called wet saturated steam or "wet steam." Its specific volume, or volume in cubic feet of one pound, and its density, or weight in pounds per cubic foot, are each constant for any definite temperature and pressure, as will be seen from the last two columns of Table 7. Just at the point when the water is completely evaporated the steam is known as dry saturated steam or "saturated steam." If further heated, it becomes superheated steam. Summarizing, we have wet steam from the time water begins to evaporate up to the time of complete evaporation; saturated steam at the moment of complete evaporation; and superheated steam when further heated.

Furthermore, saturated steam is dry steam of a temperature due to its pressure; that is, it contains no moisture, nor is it superheated. When it is heated above a temperature due to its pressure it becomes superheated.

* This illustration is given simply to convey graphically to the mind the general effect of heat; the exact values are not important.

steam. Dry steam may be either saturated or superheated. If water is injected into superheated steam it will immediately vaporize, reducing the temperature of the latter; and if sufficient water is injected the steam will be reduced to saturated steam. If cold water is injected into saturated steam some of the steam will be condensed, and the temperature and pressure of the remainder will be lowered. Wet steam contains mist or globules of moisture, but its temperature and pressure bear the same relation as that for saturated steam. Saturated steam, then, can have but one temperature for any given pressure, while superheated steam can have any higher temperature.

Superheated Steam tends to follow the laws of perfect gases, the more nearly so the farther it is removed from the point of saturation. From the laws of gases, we have,

$$pv = RT \dots \dots \dots (1)$$

In which p = pressure in lbs. per sq. in.;

v = volume in cu. ft.;

T = temp. in degrees F. above absolute zero;

R = a constant, depending upon the gas;

= foot-pounds of external work done in altering the temp. 1° under constant pressure;

= 53.2 for air;

= for any gas, 53.2 + the specific gravity of the gas, referred to air.

Saturated Steam.—The laws of saturated steam do not follow closely the laws of perfect gases, yet have a close analogy to them. The following notation and formulas are mainly those used in *Thermodynamics of the Steam Engine*,* by Prof C. H. Peabody (under whom the writer studied), and are used here with his permission. See also Tables 7 to 10.

Notation and Formulas.

F = fahrenheit (absolute zero = -460.66°F.);

C = centigrade (absolute zero = -273.7°C.);

t = temperature in degrees F. = $t_0 + 32$;

t_0 = temperature in degrees C. = $\frac{1}{5}(t - 32)$;

T = absolute temperature in degrees F. = $460.66 + t$;

T_0 = absolute temperature in degrees C. = $273.7 + t_0$;

p = pressure (above vacuum) of saturated steam in lbs. per square inch.

Observe the algebraic signs:

+ for above 0° ;
- for below 0° .

$$\log p = A - \frac{B}{T} - \frac{D}{T^2} \left\{ \begin{array}{l} \text{In which } A = 6.1007; \\ \log B = 3.43642; \log D = 5.59873; \\ \text{and using } T = t + 461.2^\circ \text{ F.} \end{array} \right.$$

q = heat of the liquid; that is, the quantity of heat, in French units (number of heat units of 426.84 meter-kgs.), required to raise the temperature of one kilogram of water from freezing (0°C.) to a given temperature t_0 ;

$$= t_0 + 0.000002 t_0^2 + 0.0000003 t_0^3.$$

$$= \int c dt, \text{ in English units.}$$

λ = total heat; that is, the quantity of heat (number of heat units of 778 ft.-lbs.) required to raise one pound of water from freezing (32°F.) to a given temperature t , and to entirely vaporize it under the pressure due to that temperature;

$$= 1091.7 + 0.305(t - 32). \text{ But see Marks and Davis formula, page 1378.}$$

r = heat of vaporization, which may be defined as the number of heat units, of 778 ft.-lbs., required to vaporize one pound of water at a given temperature under the corresponding pressure;

$$= \text{total heat} - \text{heat of liquid} = \lambda - q.$$

ρ = heat equivalent of internal work; that is, the internal latent heat or the heat units, of 778 ft.-lbs., required to do the disintegration work during the vaporization of one pound of water;

$$= r - A p u = r - A p (s - \delta);$$

where A = reciprocal of mechanical equivalent of heat,

$$= \frac{1}{J} = \frac{1}{778} = 0.00128535, \text{ and}$$

s = specific volume of saturated steam; that is, the volume in cubic feet of one pound of saturated steam.

δ = specific volume of the water.

$pu = p(s - \delta)$ = external work.

Apu = heat equivalent of external work; that is, the external latent heat or the heat units, of 778 ft.-lbs., required to overcome the external pressure, and do the work of increasing the volume from δ to s .

c = specific heat of the liquid = $\frac{dq}{dt}$.

$\int \frac{cdt}{T}$ = entropy of the liquid; the term entropy is used to denote a quality or condition of the liquid, increasing when heat is added, and decreasing when heat is subtracted; the entropy remains constant when no heat is added or subtracted; it is a very useful property in all thermodynamic calculations.*

s = specific volume, or volume in cubic feet of one pound of steam.

r = density, or weight in pounds of one cubic foot of steam;

$$= \frac{1}{s}$$

SATURATED-STEAM TABLES.—Tables 7 and 8, following, are the old tables which have been used by engineers for the past ten years. These are followed by Tables 9 and 10, which are calculated from more recent experimental data. The older tables are reproduced here simply for methods of comparison, and Tables 9 and 10 should be used because the values are more correct.

The formulas given above are the old formulas. The new formula for heat of vaporization, in English units, is

$$r = 141.124 (689 - t) 0.01249.$$

* Entropy Diagrams are very useful for this purpose. They represent, graphically, the successive thermal changes in a body due to the simultaneous variations of Temperature and Entropy—two of the coordinates characterizing the conditions of the body. In this connection it may be stated that *Total Heat* represents energy or *Work*. Now, *Work* is made up of two factors, *force* and *distance* ($W = fd$). Similarly, the *Total Heat* may be considered as made up of two factors, *temperature* and *entropy* ($H = T\theta$ or $\lambda = T\theta$); or, graphically, the total heat is the diagram area whose ordinate at the extreme right of the area considered is the temperature T , laid off from the abscissa whose value is the entropy θ ; the total heat being the summation of the vertical strips.

7.—SATURATED STEAM—ENGLISH UNITS.*

10.—REVISED Saturated Steam Table—ENGLISH UNITS.
(Condensed from Prof. Peabody's Tables.)
(Note.—See also Table 9, preceding.)

Pressure, Pounds per Square Inch.	Temperature, Degree Fahrenheit.	Heat of the Liquid.	Heat of Vap- orization.	Heat Equiva- lent of Inter- nal Work.	Heat Equiva- lent of Exter- nal Work.	Entropy of the Liquid.	Entropy of Vaporiza- tion.	Specific Vol- ume, Cubic Feet per Pound.	Density, Pounds per Cubic Foot.

Flow of Steam.—G. H. Babcock, in "Steam," gives the following formula:

Flow through pipes:
$$W = \frac{\sqrt{L(p_1 - p_2)d^5}}{L\left(1 + \frac{8.6}{d}\right)} \dots\dots\dots (1)$$

Where W = weight of steam which will flow per minute, in lbs.;

d = diameter of pipe, in ins.;

r = density or weight per cubic foot for p_1 , in lbs.;

p_1 = initial pressure, at entrance, in lbs. per sq. in.;

p_2 = pressure at end or exit of pipe, in lbs. per sq. in.;

L = length of pipe, in feet.

11.—FLOW OF STEAM THROUGH PIPES.

Initial Pressure by Gage, Pounds per Sq. In.	Diameter of Pipe, in Inches. Length of Each = 240 Diameters.

Note.—"For sizes of pipe below 6-inch, the flow is calculated from the actual areas of 'standard' pipe of such nominal diameters. For horse-power, multiply the figures in the table by 2. For any other loss of pressure, multiply by the square root of the given loss. For any other length of pipe, divide 240 by the given length expressed in diameters, and multiply the figures in the table by the square root of this quotient, which will give the flow for 1 lb. loss of pressure. Conversely, dividing the given length by 240 will give the loss of pressure for the flow given in the table."

Steam Boilers.—The Efficiency of a steam boiler is the ratio of the heat utilized in heating the water and raising steam, to the total heat generated by the combustion of the fuel; and ranges from 50 to 75 per cent., the latter being rarely exceeded. Thus, if a pound of coal has a heating value of 14,000 B. T. U. it is theoretically capable of evaporating, "from and at" * 212° F (see Table 7, preceding), $14000 \div 965.8 = 14.5$ lbs. of water; while if the efficiency of the boiler is 75 per cent., the amount actually evaporated by the pound of coal will be $14.5 \times .75 = 10.87$ lbs. of water.

One commercial horse power of a boiler is variously defined as follows:

- (1) The evaporation of 30 lbs. of water per hour from a feed-water temperature of 100 F into steam at 70 lbs. gage pressure (above atmosphere); considered equivalent to
- (2) 34.5 (34.488 exact) units of vaporization at 212° F; considered equal to
- (3) 34.5 pounds of water evaporated from a feed-water temperature of 212° F into steam at the same temperature.
- (5) From our steam table, $34.5 r = 34.5 \times 965.8 = 33,320$ B. T. U. per hour; but
- (6) 33,305 British thermal units per hour is sometimes taken as a standard (= 34.488 r , using r at 965.7).

Conclusion: (1) is used in making actual tests of boilers; the others for purposes of calculation.

* "From and at" 212° F, means that the vaporization takes place at 212° F from feed water at the same temperature. Digitized by Google

Consumption of Coal per boiler horse-power hour may be determined from the above data. Assuming the boiler at 75 per cent efficiency, one pound of coal will generate say $14000 \times .75 = 10500$ British heat units (if feed water is at $212^{\circ} F$). Then (1) the amount of coal per boiler horse-power per hour = $\frac{33\,320}{10\,500} = 3.17$ lbs. This result is also obtained (2) by dividing 34.5

by 10.87; that is, the number of pounds of water evaporated per horse-power hour, divided by the number of pounds evaporated per pound of coal, as calculated above.

In practice, we generally assume that one pound of coal will generate about 10 000 heat units, in which case it would require 3.332 pounds of coal to develop one boiler horse-power per hour, which is very close to the average performance of the Cahall boiler, Table 6, preceding. Now a boiler horse-power per hour (= 33 320 heat units or $33\,320 \times 778 = 25,922,960$ ft.-lbs.) is very different from an engine horse-power hour (see page 1363) which is equal to 1,980,000 ft.-lbs.

Thus, 1 boiler H.-P. hour = 13.0924 engine H.-P. hours,

or 1 engine H.-P. hour = 0.07638 boiler H.-P. hours.

Hence the number of pounds of coal consumption per engine horse-power, is approximately,

$$\frac{3.332 \times 0.07638 = 0.2545}{\text{Efficiency of the Engine}} \quad (\text{See also page 1363}) \dots (1)$$

provided there is no loss between the boiler and the engine.

Kinds of Steam Boilers.—In the discussion of impulse water wheels, page 1363, it is stated that the greatest amount of the energy of the jet has been imparted to the wheel when the water loses its velocity on striking the buckets. The same principle holds good in the construction of boilers. They should be so designed that the feed water shall absorb the greatest amount practicable of the heat of combustion of the fuel, with the minimum waste of gases.

Ordinary steam boilers may be classified as water-tube boilers, fire-tube boilers and flue boilers:

(1) Water-tube boilers have a large number of tubes of moderate size connected together at their ends and also with a reservoir of water above; and are placed directly over the grate or in the path of the flames. The tubes may be horizontal, vertical, inclined, straight, curved, etc. There should be no "dead" ends. They are especially adapted to high steam-pressure. Notable examples: Babcock and Wilcox, Cahall, Thornycroft.

(2) Fire-tube boilers consist of a large number of small tubes acting as flues and surrounded by the water contained in an outer shell, which requires special design. The circular tubular boiler is of this type, including locomotive boilers.

(3) Flue-boilers differ from the fire-tube boilers in that the tubes are reduced to one or more in number and greatly increased in size. If the furnace is outside the flues it is "externally fired;" if inside the flues it is "internally fired." Of the latter class the Cornish boiler has one flue, while the Lancaster has two. The Scotch marine boiler is a flue- and fire-tube boiler combined.

Boiler Settings.—The following is from the notes of J. B. Stanwood:

The brick-work about a boiler should be thick to prevent loss by radiation—a 21" wall should be used if possible. All flues and surfaces exposed to action of heat should be lined with best fire-brick. It is not a good plan to convey gases back over top of boiler, unless there is space enough for a man to enter and clean off soot. The distance from grate bars to lower portion of boiler shell should not be less than 24"; 26" and 28" are not too great, and in large shells 30" can be employed.

The bridge-wall should curve to conform to shape of boiler shell. Ten inches makes a good space between wall and shell. Back of bridge-wall the surface should be paved with hard brick, the surface dipping down to a depth at rear end of boiler of about 18" to 24" according to size of shell. The distance between back tube sheet and back wall should be 18" for a 48" shell; 24" for a 72" shell.

Boiler walls will crack, and no form of construction seems to entirely prevent this. Walls with air spaces are as liable as those without, with the danger of leaking more air when they do crack. The best method to hold

boiler walls together is with "buck-staves" or "buck-bars." The best form is railway iron with ends mashed down under a hammer, to allow for drilling holes for tie-rod. Most builders do not supply "buck-staves" unless specially ordered. The cheapest form of fire-front is the so-called "half-arch," which does not cover any more of the front of the furnace than is absolutely decent. On small boilers it is employed as a support. For a good job a "full flush front" should be used with damper plate and damper.

Boilers, now-a-days, are not set in batteries, all to work together as a unit. They are and should be set, so that each boiler is independent of the other in the battery. In this way any one can be shut down for cleaning or for repairs. This arrangement does away with the old-fashioned steam and mud-drums, which connected the boilers of a battery together. Do not buy either a mud-drum or steam drum; they are a source of trouble, danger and expense. The trade usually includes with the boiler front, the grate bars, a bearing-bar to support same, a soot or ash-door with frame, a brick arch plate or supporting bars, and a boiler stand for small boilers.

Steam Engines are steam motors, or mechanisms for converting the thermal energy of steam into mechanical work. The efficiency of an engine is the ratio of the mechanical work done, to the energy of the steam consumed in doing it; or, the ratio of the heat changed into work, to the heat applied. A *perfect heat engine*,* working to absolute zero temperature, would of course have an efficiency of 100 per cent; that is, it would be able to convert all the applied heat into work. A *"perfect" steam engine*, from a mechanical standpoint, can never be expected to exceed an efficiency of about 25 per cent. The best types of steam engines have an efficiency in actual practice of only about 18 per cent, because they cannot utilize a greater ratio of the energy of the steam delivered to them. Such engines are of the condensing- and multiple-expansion type. Non-condensing engines have efficiencies ranging from 5 to 10 per cent. Recent engines of moderate power and high superheat have attained an efficiency of 22%.

Engine Horse-Power.—Steam engines are rated by the horse-power, the unit of work being the foot-pound. 1 H.-P. second = 550 ft.-lbs.; 1 H.-P. minute = 33,000 ft.-lbs.; 1 H.-P. hour = 1,980,000 ft.-lbs.

Problem.—A steam engine working at an efficiency of 8% uses 40 lbs. of coal per hour. Assuming that each pound of coal generates 10 000 British thermal units in the steam, what horse-power is realized?

$$\text{Solution.}—\frac{40 \times 10\,000 \times 778 \times .08}{1\,980\,000} = 12.574 \text{ H.-P. Ans.}$$

In the above problem the coal consumed per horse-power per hour = $\frac{12.574}{40} = 3.18$ lbs. This result can also be obtained from equation (1);

$$\text{thus, } \frac{0.2545}{.08} = 3.18 \text{ lbs.}$$

Coal Consumption per horse-power per hour may vary from 2 lbs., for large efficient steam plants, to 4 lbs. for smaller plants, less efficient. It is well to estimate 6 or 7 lbs. for hoisting engines ordinarily used by contractors. Of course much depends upon the quality of the coal. If of poor quality the consumption will be greater.

Value of Wood as fuel.—Assuming the wood to be thoroughly air-dried, one ton of coal is equivalent to 1 cord of Douglas (Oregon or Washington) fir; 1.05 cords of hickory; 1.1 cord of maple; 1.2 cord of white oak; 1.5 cord of beech; 1.6 cord of black oak; 2.0 cords of elm; 2.1 cords of chestnut; 2.4 cords of pine. These values are necessarily approximate only. (See also page 1352.)

Principle of the Steam Engine.—An engine has one or more "cylinders." A cylinder is simply a cylindrical barrel, with closed ends, in which is fitted a piston *P* (Fig. 1) made to move back and forth by the pressure of steam admitted alternately on either side of it. The piston rod is connected, perhaps indirectly, with a crank or wheel, giving the latter a circular motion, thus producing continuous power in one direction.

* This is used in a distinct sense from the so-called "heat engines" which include gas- and oil engines. Such engines may have an efficiency of 20 per cent or more.

Fig. 1 shows a longitudinal section of the cylinder of a Corliss engine. The steam enters at the top of the cylinder through a steam pipe leading directly from the boiler, and under a pressure of say 100 lbs. (per sq. in.) more or less. (The exact pressure is registered by a pressure gage or indicator.) It enters the cylinder proper through one of the steam valves *S* or *s*.

Fig. 1.

Fig. 2.

A = Admission
A-B = Admission Line
K = Compression

and after it has performed its work of pressure and expansion it escapes through the parts *E* and *e*, at the bottom of the cylinder, into the exhaust. It may either be wasted, or condensed into hot feed-water for the boiler.

Fig. 2 shows a typical double indicator diagram for a non-condensing engine, and illustrates graphically the action of the cylinder and the working pressure on the piston at every position. The full diagram is for the pressure on the right of the piston, and the dotted diagram for the pressure on the left; the two together illustrating a complete cycle, from the starting point at the right of the cylinder to its return to that position.

Starting with the piston at the right, Figs. 1 and 2, and considering the steam pressure at the right of the piston: *A* is the point of admission of steam; *A-B* the admission line; *B* the point of initial pressure (the distance between *B* and the boiler pressure line shows the loss in pressure from the boiler to the engine); *B-C* the steam line (the valve *S* being open from *A* to *C*); *C* the cut-off, at which point the valve *S* is closed and beyond which the steam works by expansion; *C-R* the expansion line, the pressure decreasing as the volume of steam increases (this curve is very nearly a hyperbola); *R* the point of release produced by the opening of the exhaust valve at *e*; *R-X* the exhaust line; *X-K* the back-pressure line; *K* the point of compression; *K-A* the compression line. The area of this curve, *A B C R X K A*, divided by the horizontal length of figure, practically the piston stroke, gives the mean effective pressure (*M. E. P.*) per sq. in. on the right-hand side of the piston during its cycle. Similarly, the *M. E. P.* on the left-hand side of piston is obtained from the dotted diagram. Engine diagrams should be started at admission or during exhaust, otherwise they may not close.

Mean Effective Pressure (M. E. P.)—The *M. E. P.* for any particular engine should be obtained by indicator diagrams as explained above. The following table gives average *M. E. P.*'s. for non-condensing engines:

12.—MEAN EFFECTIVE PRESSURES FOR VARYING CUT-OFFS AND INITIAL STEAM PRESSURES; NON-CONDENSING ENGINES.

Initial Pressure:	$\frac{1}{16}$ Cut-off.	$\frac{1}{8}$ Cut-off.	$\frac{1}{4}$ Cut-off.	$\frac{3}{8}$ Cut-off.	$\frac{1}{2}$ Cut-off.	$\frac{3}{4}$ Cut-off.	$\frac{7}{8}$ Cut-off.	$\frac{9}{16}$ Cut-off.
40	3.65	9.05	13.46	17.34	20.75	23.70	26.22	30.50
45	5.42	11.32	16.15	20.39	24.13	27.32	30.08	34.75
50	7.19	13.59	18.85	23.45	27.50	30.94	33.95	39.00
55	8.96	15.86	21.54	26.50	30.87	34.56	37.81	43.25
60	10.73	18.12	24.24	29.56	34.24	38.18	41.68	47.50
65	12.50	20.39	26.93	32.61	37.61	41.80	45.54	51.75
70	14.27	22.66	29.63	35.67	40.98	45.42	49.41	56.00
75	16.04	24.92	32.32	38.72	44.35	49.05	53.27	60.25
80	17.81	27.19	35.02	41.78	47.72	52.68	57.14	64.50
85	19.58	29.46	37.71	44.83	51.09	56.31	61.00	68.75
90	21.36	31.72	40.41	47.89	54.46	59.94	64.87	73.00
95	23.13	33.98	43.10	50.94	57.83	63.57	68.73	77.25
100	24.90	36.26	45.80	54.00	61.20	67.20	72.60	81.50

With throttling engines results are obtained dependent upon proportion of steam-ports, travel of valve, piston speed, size of governor, and design of engine.

The theoretic mean effective pressure may be calculated by means of a formula involving the use of a table of hyperbolic logarithms. This formula assumes that the "expansion line" (see Fig. 2) is a hyperbola. It takes into consideration the point of cut-off. It is used principally in the design of engines, and only about 70 per cent of the theoretic *M. E. P.* is attained in practice.

Horse-power from mean effective pressure (M. E. P.)—

NOTATION.

D = diameter of cylinder;

A = area of cylinder = $\frac{\pi D^2}{4} = 0.7854 D^2$;

d = diameter of piston rod;

a = area of piston rod = $\frac{\pi d^2}{4} = 0.7854 d^2$;

s = length of piston stroke;

n = number of revolutions per minute.

All dimensions in inches and square inches.

Then the horse-power is—

$$\frac{[(M. E. P. \text{ for head end}) \times A + (M. E. P. \text{ for crank end}) \times (A - a)] s n}{33\,000 \times 12} \quad (2)$$

Problem.—A non-condensing engine is working at $\frac{3}{10}$ cut-off under an initial pressure (at *B*—not boiler pressure) of 90 lbs., and at a speed of 130 revolutions per minute, with a stroke of 24 inches. The diameter of cylinder is 16 ins., and of piston rod 2.5 ins. What horse-power is realized?

Solution.—From Table 12, preceding, the *M. E. P.* (for both head- and crank end) is 54.46; hence, from equation (2), the horse power =

$$\frac{54.46 \times (2A - a) s n}{33\,000 \times 12} = 170 \text{ H. P.} \quad \text{Ans.}$$

Economic Performance of Steam Engines.—The following is from the notes of J. B. Stanwood:

NON-CONDENSING ENGINES.

Slide-Valve Engine.—75 to 80 lbs. of boiler pressure; stroke, long; mean effective pressure, 33 to 38 lbs. per sq. in.; 25 to 100 H. P.; cut-off, $\frac{3}{4}$ stroke; about 40 lbs. steam per indicated H. P. per hour. When valves and piston are tight this has been reduced to 33 lbs. of dry steam per indicated horse-power (I. H. P.) per hour by careful test.

Automatic High-Speed Engines with single valves.—75 to 80 lbs. of boiler pressure; stroke, about equal to piston dia.; M. E. P., 40 lbs. per sq. in.; 50 to 150 H. P.; cut-off, $\frac{1}{4}$ stroke; about 40 lbs. steam per I. H. P. per hour. When valves and pistons are tight this has been reduced to 32 lbs. of dry steam per I. H. P. per hour. Valves difficult to keep tight.

Automatic High Speed Engines with double valves.—75 to 80 lbs. of boiler pressure; stroke $1\frac{1}{2}$ to 2 times piston dia.; M. E. P., 40 lbs. per sq. in.; 50 to 150 H. P.; cut-off, $\frac{1}{4}$ stroke; about 35 lbs. steam per I. H. P. per hour. When valves and pistons are tight this has been reduced to 30 lbs. of dry steam per I. H. P. per hour by careful test.

Automatic Cut-off Engines, of the Corliss type.—Stroke, 2 to 3 times dia. of piston; 75 to 90 lbs. boiler pressure; M. E. P., 40 lbs. per sq. in.; under 200 H. P.; cut-off $\frac{1}{8}$ to $\frac{1}{4}$ stroke, 20–30 lbs. steam per I. H. P. per hour; over 200 H. P., 27 lbs. steam per I. H. P. per hour; when valves and piston are tight, this has been reduced to $23\frac{1}{2}$ lbs. of dry steam per I. H. P. per hour by careful test.

Compound Engines.—High speed, automatic cut-off, short stroke; 110 to 120 lbs. boiler pressure; M. E. P., 25 to 27 lbs. per sq. in.; 6 expansions, 100 to 250 H. P.; 27 lbs. steam per I. H. P. per hour.

CONDENSING ENGINES.

Automatic Cut-Off Engines, of the Corliss type.—Stroke, 2 to 3 times piston dia.; 70 to 80 lbs. boiler pressure; M. E. P., 40 lbs. per sq. in.; over 200 H. P.; cut-off, $\frac{1}{8}$ stroke, about 19–20 lbs. steam per I. H. P. per hour.

Compound Engines; high speed, automatic cut-off; short stroke; 110 to 120 lbs. boiler pressure; M. E. P., 27 to 30 lbs. per sq. in.; 9 expansions; 200 to 500 H. P.; 17 to 19 lbs. steam per I. H. P. per hour.

Compound Automatic Cut-off Engines, of the Corliss type.—Stroke on high pressure cylinder, 2 to 3 times piston dia.; 135 to 110 lbs. boiler pressure; M. E. P., 24 to 14 lbs. per sq. in.; over 400 H. P.; 16 to 20 expansions; 14 to 17 lbs. of steam per I. H. P. per hour. One or two special cases, 18 $\frac{1}{2}$ lbs. of steam per I. H. P. per hour has been obtained.

COMPOUND ENGINES.

Compound Engines are devices by which high grades of expansion, and consequently high pressure of steam, can be successfully used; and the evils of leakage also can be reduced.

By expanding steam partially in one, then in a second, and perhaps a third cylinder, the internal condensation is kept small; for usually late cut-offs are employed, the advantage of which is that the surfaces of the cylinders presented for re-heating to the fresh charges of steam are small, compared with the volume of steam used; and the difference in temperature between fresh and exhausted steam is slight.

Leakage of steam with compound engines is not so serious a matter; the steam that leaks through one cylinder is caught by the second instead of being thrown away. As the cut-offs are frequently late, the slide-valve can be employed, which is the tightest of all valves.

THE EFFECT OF LOAD UPON ECONOMY OF STEAM ENGINES.

A large engine working with an extremely light load is wasteful of fuel and steam; it is worse than a small business with a large staff of expensive officers, for it has more than the fixed charges always with it. A small engine overloaded may be an annoyance and care, but if in good condition it may be economical in fuel.

Steam Pumps.—Fig. 3 shows a longitudinal section of a Worthington direct-acting duplex steam pump. It is "direct-acting" because the plunger of the pump (on the right) is directly connected to the piston rod of the engine (on the left). It is "duplex" because two of the pumps are placed side by side, each one of which is connected by links and a rocker to the valve of the other. As the plunger works back and forth the water is sucked through the valves at the bottom, at either end, while the water previously sucked at the opposite end is at the same time forced through the upper valves into the discharge *D*.

Duplex Pumps are durable and easy acting, and are used for all classes of pumping.

Centrifugal Pumps consist essentially of a pump wheel or impeller with curved vanes which move tightly in an outer casing. The wheel is fixed

Fig. 3.—Worthington Steam Pump (p. 1366).

on a shaft rotated by a belt running over a pulley. In a side-suction pump the water enters on either side at the center of the wheel and is forced out at the periphery through a tangential outlet from the casing. Centrifugal pumps are economical in raising water against low heads,

Fig. 4.—Centrifugal Pump.

say up to 30 ft., more or less; reciprocating pumps are more efficient for high heads.

Rotary Pumps are operated by two rotating valves in "gear," each moving tightly in an outer casing.

Duty of Pumps.—The duty of a pump was formerly tested and measured by the number of foot-pounds of work which it was capable of performing from the combustion of 100 pounds of coal used. As the quality of coal varies a new standard was proposed, in 1891, by a Committee of the A. S. C. E.:*

$$\text{Duty} = \frac{\text{No. of foot-pounds of work done} \times 1\,000\,000}{\text{Number of heat units consumed}}$$

This would be equivalent to the old rule, provided 100 lbs. of coal will generate 1 000 000 (100 × 10 000) heat units (see page 1362) to the water in the boiler, a result which can generally be obtained.

D.—HEAT (INTERNAL-COMBUSTION) ENGINES.

TESTS OF INTERNAL-COMBUSTION ENGINES ON ALCOHOL FUEL.

(Digest of Bulletin 191, U. S. Dept. of Agric.)

Introduction.—Recently in this country great interest has developed in the possibilities of alcohol as fuel, and the question of its being used as a substitute for the petroleum fuels will become of increasing importance as time goes on. The supply of crude oil to be obtained in the United States must ultimately diminish, and the history of the past indicates that a constant increase in price of kerosene and gasoline may ultimately be expected. On the other hand, it is not improbable that the price of alcohol may fall, so that as regards cost alcohol may be used advantageously in comparison with the petroleum oils.

Specific objects of the investigation.—First, to determine whether the gasoline and kerosene engines at present on the American market can run on alcohol as fuel; the manipulation to be followed in making the engines run on alcohol; the measurement of the relative maximum powers of the engines when using alcohol and the fuels for which they were originally made; and the relative consumptions of the different fuels. Second, to determine as far as possible the improvements which might be desirable in the design of engines manufactured especially for alcohol.

Outline of the ground covered by the tests.—The engines used, and range of tests, were:

- No. 1. Gasoline engine, 15 h. p. at 280 rev. per min.; 2 cyl., single-acting, vertical, 4 cycle, 6½" bore, 10" stroke. 15 tests reported, giving consumption of alcohol and gasoline under different brake loads and with different initial compressions. Lowest consumptions obtained were 0.71 lb. (0.12 gal.) of gasoline and 1.12 lb. (0.16 gal.) of alcohol per brake h. p. hour. The highest working m. e. p. obtained was about 90 lbs. with both gasoline and alcohol, but at best consumption the m. e. p. were considerably lower.
- No. 2. Gasoline engine, 6 h. p. at 300 rev. per min.; 1 cyl., water-cooled, horizontal, 4 cycle, 5½" bore, 9" stroke. 24 tests with gasoline and 30 with alcohol. Highest mechanical efficiencies were 86% for gasoline and 90% for alcohol.
- No. 3. Gasoline engine, 6 h. p. at 340 rev. per min.; 1 cyl., horizontal, 4 cycle, 5½" bore, 10" stroke. 18 tests with gasoline and 19 with alcohol. Best consumption with gasoline was 0.85 lb. (0.14 gal.) per brake h. p. hour; and with alcohol, at 320 r. p. m., 1.25 lb. (0.18 gal.).
- No. 4. Gasoline engine, 6 h. p. at 350 r. p. m., 1 cyl., vert., 4 cycle, 6" bore, 8" stroke. 11 tests on gasoline and 26 on alcohol; and also the effect of heating the air in advance of its entrance to the carburetter. Best alcohol consumption was 1.13 lb. (0.17 gal.) per brake h. p. hour; and with air entering the carburetter heated to 125° F., the engine would self-ignite, the m. e. p. at best consumption being 93 lbs.
- No. 5. Kerosene engine, 6 h. p. at 360 r. p. m., 1 cyl., horizontal, 2 cycle with crank case compression, cyl. dia. 7" with 8" stroke. The engine has no carburetter, but is fitted with a separate vaporizing chamber. Oil is supplied to a pump on top of the engine, which delivers it directly through a pipe to the vaporizer lip, and has a hand-operated handle to deliver oil in starting. Four tests were made with kerosene and 5 with alcohol. The best consumption with kerosene was 0.98 lb. (0.15 gal.), and with alcohol 1.60 lb. (0.23 gal.).
- No. 6. Automobile gasoline engine, 40 h. p. at 900 r. p. m., 4 cycle, 4 cylinder, single acting, vertical, 4½" bore, 5½" stroke. All valves are cam operated and the carburetter is of the constant level type. Two tests each were made with gasoline and alcohol. The result of these tests is as follows:

No. of Test	Kind of Fuel.	Brake Load.			Revolutions per minute.	Brake horse-power.	Duration of Test.	Fuel consumption			Vacuum in carburettor.
		W	w	W-w				Per Hour	Per Horse-power Hour		
		Lbs.	Lbs.	Lbs.			Min/Sec	Lbs.	Lbs.	Gallon.	Inch. of Mercury.
153	Gasoline	215	25	190	660	26.3	2 19	24.2	0.92	0.16	to 1
154	do	200	22	178	780	29.2	8 0	29.9	1.02	.17	to 1
155	Alcohol	218	24	194	680	27.7	10 0	37.9	1.37	.20	to 1
156	do	220	26	194	670	27.3	19 0	39.2	1.44	.21	to 1

in which $W - w$ is the force used in computing the brake horse-power.

No. 7. Automobile gasoline engine, 40 h. p. at 900 r. p. m., 4 cycle, 4 cylinder, $4\frac{1}{2}$ " bore, $5\frac{1}{2}$ " stroke. Twelve tests with gasoline and 7 with alcohol. The best consumption with gasoline was 0.69 lb. (0.12 gal.) per brake h. p. hour; with alcohol 1.30 lb. (0.19 gal.).

No. 8. Boat gasoline engine, 2 h. p. at 700 r. p. m., 1 cyl., vertical, 2 cycle, $4\frac{1}{2}$ " bore, 4" stroke. Ten tests with gasoline and 7 with alcohol. Best consumption on gasoline was 1.36 lb. (0.23 gal.) per brake h. p. hour; and with alcohol 2.52 lb. (0.37 gal.).

Conclusions.—The following conclusions are drawn as a result of the investigations:

(1) Any gasoline engine of the ordinary types can be run on alcohol fuel without any material change in the construction of the engine. The only difficulties likely to be encountered are in starting and in supplying a sufficient quantity of fuel, a quantity which must be considerably greater than the quantity of gasoline required.

(2) When an engine is run on alcohol its operation is more noiseless than when run on gasoline, its maximum power is usually materially higher than it is on gasoline and there is no danger of any injurious hammering with alcohol such as may occur with gasoline.

(3) For automobile air-cooled engines alcohol seems to be especially adapted as a fuel, since the temperature of the engine cylinder may rise much higher before auto-ignition takes place than is possible with gasoline fuel; and if auto-ignition of the alcohol fuel does occur no injurious hammering can result.

(4) The consumption of fuel in lbs. per brake H. P., whether the fuel is gasoline or alcohol, depends chiefly upon the H. P. at which the engine is being run and upon the setting of the fuel supply valve. It is easily possible for the fuel consumption per H. P. hour to be increased to double the best value, either by running the engine on a load below its full power or by a poor setting of the fuel supply valve.

(5) These investigations also showed that the fuel consumption was affected by the time of ignition, by the speed, and by the initial compression of the fuel charge. No tests were made to determine the maximum possible change in fuel consumption that could be produced by changing the time of ignition, but when near the best fuel consumption it was shown to be important to have an early ignition. So far as tested the alcohol fuel consumption was better at low than at high speeds. So far as investigated, increasing the initial compression from 70 to 125 lbs. produced only a very light improvement in the consumption of alcohol.

(6) It is probable that for any given engine the fuel consumption is also affected by the quantity and temp. of cooling water used and the nature of the cooling system, by the type of ignition apparatus, by the quantity and quality of lubricating oil, by the temp. and humidity of the atmosphere, and by the initial temp. of the fuel.

(7) It seems probable that all well-constructed engines of the same size will have approximately the same fuel consumption when working under the most advantageous conditions.

(8) With any good small stationary engine as small a fuel consumption as 0.70 lb. of gasoline, or 1.16 lbs. of alcohol per brake H. P. hour may reasonably be expected under favorable conditions. These values correspond to 0.118 and 0.170 gallon respectively, or 0.95 pint of gasoline and 1.36 pints of alcohol. Based on the high calorific values of 21,120 British thermal units per pound of gasoline and 11,880 per pound of alcohol, these consumptions represent thermal efficiencies of 17.2% for gasoline and 18.5% for alcohol.

But calculated on the basis of the low calorific values of 19,660 B. T. U. per pound of gasoline and 10,620 for alcohol, the thermal efficiencies become 18.5 for the former fuel and 20.7 for alcohol. The ratio of the high calorific values used above is, gasoline to alcohol, 1.78. The corresponding ratio of the low calorific values is 1.85. The ratio of the consumptions mentioned above is, alcohol to gasoline, 1.66 by weight, or 1.44 by volume.

Properties of Liquid Fuels.—All liquid fuels available for commercial use are complicated mixtures of many different chemical substances, and hence are always liable to more or less change in chemical composition. Gasoline and kerosene are most easily examined by their specific gravities, but since each is a mixture of numerous lighter and heavier oils, a definite constant density is not a guarantee that the composition may not change sufficiently to affect the action of the fuel in an engine.

Commercially pure grain or ethyl alcohol is sensibly pure except for the water which may be mixed with it. In this country alcohol is described according to its strength by stating the percentage of absolutely pure alcohol, by volume, which exists in the mixture of alcohol and water. Thus, 90% alcohol contains 90% alcohol and 10% water by separate volume. Since alcohol is lighter than water, the stronger the alcohol the lighter the specific gravity, and 90% alcohol contains less than 90% of alcohol by weight. Moreover, since when pure alcohol and water are mixed the volume of the mixture is less than the sum of the volumes of the water and alcohol before mixing, 90% alcohol contains more than 10% of water by volume. A U. S. "proof" gallon contains 50% alcohol by volume, the remainder of the mixture being water; hence a quantity of alcohol when stated in proof gallons is expressed by a number just twice as large as it would be if stated in gallons of 100% alcohol.

The denatured alcohol which may be used in engines in the U. S. must be prepared as follows, according to the regulations of the Commissioner of Internal Revenue: To 100 volumes of ethyl or grain alcohol of a strength not less than 90% there must be added either 10 volumes of methyl or wood alcohol and $\frac{1}{2}$ of 1 volume of benzine or 2 volumes of methyl alcohol and $\frac{1}{2}$ of 1 volume of pyridin bases. The substances added to the grain alcohol will probably not be of uniform quality, and hence there will be some variability in the properties of the denatured alcohol which will affect its use as a fuel. The following figures are fair average values of the different fuels:

Substance.	Spec. Grav.	Lbs. per Gallon.	Substance.	Spec. Grav.	Lbs. per Gallon.
Gasoline.....	0.71	5.9	95% ethyl alcohol....	0.82	6.8
Kerosene.....	0.80	6.7	90% ethyl alcohol....	0.83	6.9

The two most important properties of a liquid fuel, which determine its availability or adaptability for use in an engine, are its heat of combustion and its volatility.

Heat of Combustion.—For the various petroleum oils the heat of combustion varies between 19 000 and 21 000 B. T. U. per lb. of oil, and 20 000 is an average value; for pure alcohol, about 12 700 B. T. U. per lb.

All liquid fuels contain a considerable proportion of hydrogen, which when burned forms water in the condition of steam. When the fuel is burned in a calorimeter this steam is condensed by the cold water surrounding the calorimeter and in this condensation contributes a considerable amount of heat to the total amount absorbed by the cold water. When a fuel is burned in an internal-combustion engine the products of combustion

always leave the engine cylinder at a temperature much above the boiling point of water; hence the engine is unable to make use of the latent heat of condensation of the steam formed in combustion, although this latent heat is included in the heat measured by the calorimeter. On this account it is customary, in comparing fuels used in explosion engines, to calculate the heat of condensation of the steam in the products of combustion and to deduct this amount from the heat of combustion as measured in the calorimeter, giving what is called the low value of the heat of combustion. Correspondingly, the heat as measured by the calorimeter is called the high value of the heat of combustion.

Air Necessary for Combustion.—When a fuel has a definite chemical composition, the air necessary for its combustion can be exactly calculated. Hence, this calculation can be made for pure methyl or ethyl alcohol, but can be made only approximately for a fuel like gasoline, which is a mixture of variable proportions of a large number of different chemical substances. By the formula for ethyl alcohol, C_2H_5OH , its molecular weight is 46: carbon 24 ($=12 \times 2$) + hydrogen 6 ($=1 \times 6$) + oxygen 16 ($=16 \times 1$) = 46. For the complete combustion of 1 molecule of alcohol the two atoms of carbon require 4 atoms of oxygen to form carbon dioxide, and the 6 atoms of hydrogen require 2 atoms of oxygen, in addition to the 1 atom present, to form steam, thus making 6 atoms of oxygen in all to be supplied. The weight of the 6 atoms is $6 \times 16 = 96$. Hence complete combustion of 1 lb. of C_2H_5OH requires $96 \div 46 = 2.086$ lbs. of oxygen. In one pound of pure dry air there is 0.230 lb. of oxygen, so that the combustion of 1 lb. of C_2H_5OH requires $2.086 \div 0.230 = 9.06$ lbs. of air, or about 119 cu. ft. of pure air at a temp. of 60° and at sea level. If the alcohol contains water, 1 lb. of the alcohol-water mixture requires less air than that stated. If the air is moist, 1 lb. of it contains slightly less than 0.230 lb. of oxygen and hence more air would be required.* In an actual engine the amount of air is proportioned to the amount of vapor, not by any exact measurement of either, but by trial to secure either the best results in maximum power or in minimum fuel consumption.

Vaporization of Fuel.—Before any liquid fuel can be used in the usual form of explosion engine, it must be vaporized, and this vapor must be mixed with air in proper proportions. Thus the preparation of the combustible mixture involves three steps: First, vaporization of the fuel; second, mixture of the fuel vapor and air; and, third, the proper adjustment of the proportions of fuel and air.

The differences in the devices used in engines to accomplish these objects constitute the widest variations in the detailed design of existing engines. In some of these devices the fuel is boiled in a separate chamber, called a vaporizer, from which the vapor flows into a stream of air entering the engine, the amount of vapor being regulated by a valve just as in the case of an engine using illuminating or producer gas.

In another type of vaporizer the fuel is dropped on a hot plate over which the air flows, the proportion of fuel being regulated by the amount of liquid fuel forced against the plate. Kerosene requires a high heat to vaporize it completely, since its boiling point is high, and hence it is much used with vaporizers of the hot-plate type. Alcohol will work satisfactorily with a vaporizer of this type if the temperature of the hot plate is properly regulated.

Gasoline is easily vaporized at ordinary atmospheric temperatures and hence requires no hot plate or heated vaporizing chamber. Usually the liquid gasoline is admitted directly into the air entering the engine through a device known as the carbureter, which is intended to regulate the proportion of fuel and to spray it uniformly through the mass of air so that as the liquid spray turns into vapor it will produce a homogeneous mixture of air and vapor. Alcohol can also be used in a gasoline carbureter.

As with all substances which liquefy at ordinary temperatures, there is a definite limit to the amount of alcohol vapor which can exist in a cubic foot of space at any given temperature. Assuming the laws for perfect gases to hold, at any given constant temperature the weight of alcohol vapor present in a cubic foot of space is proportional to its vapor pressure and is usually measured or represented by this vapor pressure. This may be

* Approx. results calculated in a similar manner for various petroleum fuels may be found in Sorel's *Alcohol Engines*.

illustrated by imagining a cylinder provided with a tight piston and containing alcohol vapor at a pressure corresponding to 10 millimeters of mercury and kept constantly throughout the experiment at a temperature of 70°F. If now the vapor is compressed by the piston until its volume is reduced one-half, the vapor pressure will rise to 20, there being of course twice as much vapor per cubic foot of space occupied as there was originally. If the volume is again halved the pressure will rise to 40. But if the compression is continued until the vapor pressure rises to 47 millimeters of mercury a change takes place in the action. The pressure will not rise above 47 if the temperature is kept at 70°. If the piston is moved a further amount, so as to reduce the volume still more, part of the alcohol vapor will be condensed into liquid, but the vapor pressure will remain the same and the amount of vapor per cu. ft. of space will remain constant. Hence there is a definite maximum amount of alcohol vapor which can exist in a cu. ft. of space at any given temperature. It is important to remember that the space may contain any smaller amount with a correspondingly lower vapor pressure, but can not contain a greater amount than the quantity corresponding to the saturated state.

The vapor pressure of saturation increases rapidly with the temperature, and the values as determined by experiment for alcohol and some other substances at various temperatures are given in Table 13, next page.

When different gases or vapors exist simultaneously in the same space if they have no chemical action on each other, each one acts by itself just as though no other gas were present. Thus if air were also present in the cylinder used in the illustration above, the oxygen and nitrogen would not interfere at all with the action of the alcohol vapor. But it is to be noted that in such a case the pressure as measured by the barometer column or pressure gauge would be the sum of the separate pressures due to the air and due to the alcohol vapor. If moisture were present it would probably have some effect on the alcohol-vapor pressure, because water and alcohol have certain affinity for each other. On page 1371 it was shown that in a mixture of alcohol vapor and air the proportion for complete combustion of the alcohol should be 9.06 lbs. of air to 1 lb. of alcohol. If less air is present the alcohol cannot be completely consumed and the excess passes off as alcohol or some substance formed by the partial decomposition of the alcohol molecule. If more air is present than the required amount no harm is done provided the excess is not too great, and it is in fact better so far as economical consumption of fuel is concerned to have some excess of air present.

The vapor pressure of alcohol vapor in the theoretically best mixture of it with air may be calculated as follows: By Avagadro's law, for the same pressure and temperature, the densities of gases are proportional to their molecular weights. Since the molecular weight of hydrogen is 2, the density of ethyl alcohol vapor is 46 ÷ 2, or 23, compared with hydrogen. Hence 1 lb. of alcohol vapor occupying any stated volume has a vapor pressure equal to

$\frac{1}{23}$ of the vapor pressure of 1 lb. of hydrogen occupying the same volume.

Likewise, since the density of air is 14.44 compared with hydrogen, 9.06 lbs. of air occupying the same stated volume has a vapor pressure equal to

$\frac{9.06}{14.44}$ of the vapor pressure of 1 lb. of hydrogen occupying the same volume.

Therefore the relative vapor pressures of the alcohol vapor and air are as $\frac{1}{23}$ and $\frac{9.06}{14.44}$, or as 0.0435 and 0.627, respectively. But $0.0435 + 0.627 =$

0.670. Hence, of the total vapor pressure produced by the mixture, $\frac{435}{670}$

or 6.5%, is due to alcohol vapor, and $\frac{627}{670}$, or 93.5%, is due to the air.

If the mixture is under the ordinary atmospheric pressure of 14.7 lbs. per sq. in., or under 760 mm. of mercury, the vapor pressure of the alcohol in the combustible mixture is 0.065 times 14.7 or 0.955 lb. per sq. in., or 0.065 times 760, or 49.4 mm. of mercury. Similarly, the pressure of the air is 0.935 times 14.7, or 13.74 lbs. per sq. in., or 0.935 times 760, or 711 mm. of mercury.

Table 13, following, contains the vapor pressure of saturation, in mm. or mercury, for pure ethyl or grain alcohol, pure methyl or wood alcohol, a sample of gasoline, and water, at various temperatures:

13.—VAPOR PRESSURE OF SATURATION FOR VARIOUS LIQUIDS.*

Temperature.		Vapor Pressure of Saturation in Millimeters of Mercury			
		Pure Ethyl Alcohol.	Pure Methyl Alcohol.	Water.	Gasoline.
°C.	°F.

65	149	437	761	187	739

* The values for ethyl and methyl alcohol are taken from the Smithsonian physical tables, the values for water from the steam tables in general use, and the values for gasoline, which were based upon tests of a sample of French commercial gasoline, are taken from Sorel's book on alcohol engines. Since gasoline is a variable substance, the values given for it are to be considered as only generally representative.

From the above table it is evident that ethyl alcohol can have a vapor pressure of 49 mm. only if its temp. is 72° F. or higher. Hence, a mixture of air and the alcohol vapor in the theoretical proportions for perfect combustion can not exist at a temp. below 72° F. A combustible mixture with some excess of air can exist at lower temperatures, as also a mixture in which a part of the alcohol is not in the form of vapor, but is carried with the air mechanically in the liquid form as a spray or fog.

The table shows that methyl alcohol vaporizes much more readily than ethyl alcohol, and gasoline much more readily than either. A mixture of different fuels will usually have a higher vapor pressure than either of the separate ingredients unless one is present in too small a quantity to produce saturation.

Since alcohol, as used commercially, is always mixed with some proportion of water, a combustible mixture formed by the vaporization of such alcohol may become saturated with the water vapor before it is saturated with alcohol, and this may retard the complete vaporization of the alcohol. Such a state is more likely to occur if the air originally contains a considerable amount of water vapor—that is, if the relative humidity is high. In such a case a temp. higher than 72° would be necessary to maintain the required amount of alcohol vapor in the mixture.

In order that alcohol may change from a liquid to a vapor it must receive a large amount of heat either from the air with which it mixes or from the metal parts of the carburetter with which it comes in contact. The hotter these parts the more quickly the alcohol can absorb the requisite amount of heat. But if the air is too hot there is danger that the mixture of air and alcohol vapor produced may be too rich in alcohol and some of the vapor must remain unburned. Still, if the air be moist, or the alcohol contain water, or the time allowed for vaporization be too short, the temp. of the air must be higher than 72° to form a proper explosive mixture.

Air at any temp. will take up some alcohol vapor, and the higher the temp. the quicker it will take up the amount necessary for the best explosive mixture. In the case of incomplete vaporization, some of the fuel may be carried along asspray, which may or may not be vaporized in the cylinder on the compression stroke. If not, it certainly will be vaporized after the explosion of the rest. It would seem desirable, therefore, to heat considerably the air supplied to an alcohol carburetter. But too much heating of the air will bring about a bad effect on the engine, because it will make the charge hotter at the end of compression, and thus decrease the weight of

the charge in the cylinder. The h. p. of the engine, other things being equal, will be decreased in direct proportion as the density of the charge is lowered by this heating, so that heating of the air before carburetting is good for complete vaporization, but bad if carried too far in its effects on power reduction.

Methods of Testing.—Each engine tested was fitted with a suitable brake for absorbing the power developed. No. 1 was provided with a special water-cooled pulley, attached to the fly wheel. The pulley had an internal rim for retaining the cooling water and an external rim for retaining the brake in place. The latter was formed of wooden blocks, attached to a belt whose length could be adjusted by a screw. A wooden arm, connected to the belt, rested upon platform scales. On all the slow-speed engines similar wooden block band brakes, bearing upon platform scales, were used.

Each automobile engine was fitted with a special water-cooled pulley, attached to its fly-wheel. The pulley was made by cutting out a disk of boiler plate, which was bolted to the fly wheel. The outside face of the disk was grooved to receive the rim of a standard cast-iron belt pulley 5" wide. The other edge of the pulley rim was fitted to another ring of boiler plate in a similar manner. Bolts passed from plate to plate. A rope break was used on this pulley, and each end of the rope was fastened to a spring scale, which in turn was suspended from the arm of a beam pivoted to a standard. The other end of the beam was held by a chain block. A movement of the chain block increased or decreased the tension on the rope. The rotation of the engine tended to pull one side tighter than the other, just as in the case with a windlass. A heavy scale, capable of recording 400 lbs., was attached to the beam near its center and carried the tight side of the rope. The other end of the rope was attached to a lighter scale, capable of recording a maximum of 24 lbs. With this brake a 200-lb. pull was registered on the heavy scale, with only 8 lbs. on the smaller scale, and the tension could be quickly and rapidly varied by the chain block.

The speed of the engines was obtained by actual counting, using a stop watch, by a hand speed counter and by a tachometer. Usually the speed was determined by more than one observer, so as to reduce the chances of error.

The ordinary formula was used for computing the brake horse-power.

$$BHP = \frac{2 \pi RWN}{33,000},$$

in which R = the brake arm in feet, W = the brake load in pounds, and N = the number of revolutions per minute.

On all the slow-speed engines, indicator cards were taken not only for the purpose of determining indicated horse-power but also for studying the characteristics of the combustion, compression, and other conditions in the cylinder. For this use a new outside spring indicator was loaned for these tests by the manufacturers of the indicator.

It was difficult to determine the proper mean effective pressure to use in computing indicated horse-power, because successive strokes often gave indicator diagrams of very different size and shape. This was shown on some of the cards reproduced later. Hence it was impossible to determine exactly the average mean effective pressure for a stated period of time. This difficulty was avoided so far as possible by taking a large number of cards. When there were numerous differing cycles drawn on one sheet, usually the planimeter point was moved around on a line as near the average of the different cycles as could be determined by eye. This gave a sort of graphical average which seemed the best that could be done under the circumstances. In certain cases, explained in detail as they arise, cycles of different size were separately measured and the different areas were used in computing the indicated horse power. No attempt was made to measure the area of the lower or suction loop on the indicator cards with the planimeter; the mean effective pressure is based upon the measured area of the upper loop only.

The number of explosions per minute was determined in hit-and-miss governed engines both by counting the number of fuel admissions and also by listening to the exhausts. This dual method is necessary because, under certain circumstances, a charge may miss fire and an explosion may be recorded from observations of fuel admissions where one did not really occur.

The indicated horse-power was computed by the usual formula,

$$IHP = \frac{PLAN}{33,000}$$

in which P = mean effective pressure in lbs. per sq. in., L = stroke of piston in feet, A = area of piston in sq. ins. and N = number of explosions per minute.

The engines were in all cases piped for alcohol fuel and also for either gasoline or kerosene, so that one could be switched on and the other off at any time. In addition a third connection was provided for the measuring tanks. Any variation in the adjustment of the engine was secured when using the permanent supply tanks before switching on the measuring tanks, and care was exercised to insure that there was no residue between the valve and the engine itself before measurements were taken.

Two methods of measuring fuel were used: (1) by noting the drop in level in a glass gage attached to a tank; and (2) by the use of a large glass beaker on a small spring platform scale, which could be read to tenths of an ounce.

Fuels used.—The alcohol used in tests was bought on competitive bids as 95% commercial alcohol and cost in barrels 38½ cents per wine gallon without the tax.

An ultimate analysis of the alcohol gives the following composition:

	Per cent.
Carbon.....	47.6
Hydrogen.....	12.7
Oxygen (by difference).....	39.7

As received the alcohol had a spec. grav. of 0.82 at 60° F., corresponding to about 91.1% by weight or 94% by volume, according to the Smithsonian physical tables. It was tested in the chemical laboratory in the usual way to determine the percentage of alcohol present after treatment to eliminate impurities, as follows:

Twenty-six grams were diluted with water, redistilled, and the amount of alcohol in the distillate determined. From this the percentage by weight in the original sample was calculated. Using Richard's tables the result obtained was 93.1%. Using Morley's table, published in the journal of the American Chemical Society, October, 1904, the result obtained was 91.4%.

The ultimate analysis indicates a slightly smaller proportion of alcohol, since a strength of 91.3% would have the following composition:

	Per cent.
Carbon.....	47.6
Hydrogen.....	12.9
Oxygen.....	39.5

These discrepancies, illustrating the difficulties of accurate determinations, even with suitable facilities and skillful observers, show the impossibility of obtaining more than approximate results except under exceptionally favorably circumstances.

The percentage of alcohol found in a sample is always likely to be greater when determined chemically than when determined by the hydrometer, because the presence of impurities in the way of solids dissolved in the alcohol or as any of the series of higher alcohols tends to make the spec. grav. of the sample greater and hence indicate too low a percentage of alcohol.

The calorific power or heat of combustion of the alcohol used in these tests was found by calorimeter determinations to be 11,880 British thermal units per pound, high value. The corresponding low value is 10,620.

Using the customary values of calorific power of 14,500 for carbon and 62,000 for hydrogen, the high heat value of combustion for pure alcohol would be by calculation 12,950. The Smithsonian physical tables give 12,930 as the value for pure alcohol on the authority of Favre and Silbermann, which would correspond to 11,800 for 91.3% alcohol.

The gasoline used in the experiments, known as "motor gasoline," was bought in New York City at 15 cents a gallon by the barrel and had a spec. grav. of about 0.71 at 60° F. Its ultimate composition was as follows:

	Per cent.
Carbon.....	85.0
Hydrogen.....	14.8

Total..... 100.8

Its heat of combustion, high value, as determined by the calorimeter, was 21,120 B. T. U. per pound. The corresponding low value is 19,660.

Using, as before, 14,500 for carbon and 62,000 for hydrogen, the calculated high heat value would be 21,500.

To show the nature of the complex mixture forming the gasoline, 150 cubic centimeters was distilled and collected in fractions of 10 cubic centimeters each. The temperatures required for the distillation of the successive fractions are shown in the following table:

• 14.—FRACTIONAL DISTILLATION OF GASOLINE.

Number of Fraction.	Temperatures.		Number of Fraction.	Temperatures.	
	°C.	°F.		°C.	°F.
1.....	46 to 60	114.8 to 140.0	8.....	97 to 100	206.6 to 212.0
2.....	64 to 75	147.2 to 167.0	9.....	100 to 104	212.0 to 219.2
3.....	75 to 80	167.0 to 176.0	10.....	104 to 108	219.2 to 226.4
4.....	80 constant	176 constant	11.....	108 to 112	226.4 to 233.6
5.....	80 to 86	176.0 to 186.8	12.....	112 to 120	233.6 to 248.0
6.....	86 to 92	186.8 to 197.6	13.....	120 to 126	248.0 to 258.8
7.....	92 to 97	197.6 to 206.6	14.....	126 to 140	258.8 to 284.0
			15.....	140 to 155	284.0 to 311.0

From this table it appears that when distillation began the vapor showed a temp. of 46° C. or 114.8° F. and that the distillation was stopped at a temp. of 155° C. or 311° F., and that at this temp. there was left 5 cu. cm. that had not yet been vaporized.

The kerosene used for testing had a spec. grav. of about 0.800 at 60° F. It was assumed to have the same heat of combustion as the gasoline used.

In making computations on the results of the tests, the following weights were used.

Substance.	Spec. Grav.	Lbs. per Gallon	Lbs. per Pint.	Pints per Lb.	Substance.	Spec. Grav.	Lbs. per Gallon	Lbs. per Pint.	Pints per Lb.
Water.....	1.000	8.33	1.04	0.96	Gasoline..	0.710	5.91	0.74	1.35
Alcohol....	0.820	6.83	0.85	1.17	Kerosene..	0.800	6.66	0.83	1.20

*K=conductance per hour; $C=\frac{1}{K}$.

Gas Engine Principles and Management (By E. W. Roberts. Eng. News, Sept. 17, 1903).—Illustrated.

Notes on the Arrangement and Construction of Steam Pipes and Their Connections (By R. C. Monteagle. Paper, Soc. of Nav. Arch. and Mar. Engr.; Eng. News, Nov. 26, 1903).—Illustrated.

Staybolts, Braces and Flat Surfaces in Boilers (By R. S. Hale. Paper, Am. Soc. M. E., Dec., 1904; Eng. News, Dec. 15, 1904).—Discussion and tables.

The Use of Superheated Steam in Locomotive Boilers (By H. H. Vaughan. Paper, Am. Ry. M. M. Assn., June, 1905; Eng. News, June 21, 1905).

Modern Problems in Gas Engineering (By Fred B. Wheeler. "Wisconsin Engineer," Dec., 1905; Eng. News, Jan. 11, 1906).—Includes table of standard gases.

The Storage of Coal by Submergence in Salt Water (Eng. News, Aug. 23, 1906).

The Use of Oil Fuels for Locomotives (Com. Rept. Trav. Engrs. Assn., Aug., 1906; Eng. News, Jan. 10, 1907).—Illustrations of the Booth, Sheedy and Lassoe-Lovekin oil burners.

Comparative Cost of Gasoline, Gas, Steam and Electricity for Small Powers (By W. O. Webber. Eng. News, Aug. 15, 1907).—Diagram. See, also, in same issue, article by F. W. Ballard, entitled "Relative Economy of Steam and Gas Power Where Exhaust Steam is Used for Heating."

The Solution of Steam Problems by the Use of a Diagram (By Lionel S. Marks, "Steam Tables and Diagrams." Eng. News, Aug. 26, 1909).—The diagram is 12 x 15 ins. and may be used in solving steam problems, of which numerous examples are given. The old equation (Regnault's) for the total heat of dry and saturated steam is,

$$H = 1091.7 + 0.305 (t - 32);$$

The Marks and Davis equation for the range of temperature from 212° to 400° F. is,

$$H = 1150.3 + 0.3745 (t - 212) - 0.000550 (t - 212)^2.$$

Below 212° the new values are well fixed by a number of individual determinations, but have not been represented by any simple equation.

Unique Direct-Acting Explosion Pump (Eng. News, Dec. 2, 1909).—Developed by H. A. Humphrey, an English engineer. This pump has neither piston nor cylinder, strictly speaking: as the water serves as the one and the waterway the other. The pumping is done with approx. 1 lb. of coal per water horse power in comparison with 2 lbs. for compound high-duty steam engines, 1.7 lbs. for triple-expansion engines, and 1.6 lbs. for a gas-engine driving a centrifugal pump. Described and illustrated, with tables of duty. It is possible that this type of pump might prove highly efficient in connection with hydraulic dredging.

70.—ELECTRIC POWER AND LIGHTING.

Electricity as a Form of Energy.—Under Steam and Gas Power (page 1347) we have seen that heat and mechanical work are mutually convertible; that is, 1 heat unit (B. T. U.) is equivalent to 778 ft.-lbs. of work, or 1 ft.-lb. of work = 0.001285 heat unit. We will now show that mechanical-, thermal-, and electrical work- and power units are mutually convertible, or have definite relations to each other.

The Electric Power Unit is the *watt*, equivalent to a flow or "current" of 1 *ampere* under a "pressure" of 1 *volt*. Thus, 60 watts means 60 volt-amperes, or a current of 10 amperes at a pressure of 6 volts, or 15 amperes at 4 volts, etc. $\text{Watts } (P) = \text{volts } (E) \times \text{amperes } (C)$. Moreover, $1 \text{ watt} = \frac{1}{746} \text{ horse-power} = 0.7373 \text{ ft.-lb. per second} = 44.238 \text{ ft.-lbs. per minute} = 265.428 \text{ ft.-lbs. per hour}$. Note that the watt does not represent work but the *rate* of work, or power. The watt-second, minute, or hour is equal to $\frac{1}{746}$ horse-power second, minute or hour, when applied to work. The watt unit, being small, is generally supplanted by the *kilowatt* in the design and rating of electric power plants and machines. (See Tables 34 and 35, Sec. 4, page 88, etc.; also Tables 1 and 2, Sec. 69, page 1348, etc.)

The Kilowatt, K.-W. (= 1000 watts) = $1000 \times .7373 = 737.3 \text{ ft.-lbs. per second} = 44,238 \text{ ft.-lbs. per minute} = 265,428 \text{ ft.-lbs. per hour}$; which is equivalent to 1.3405 horse power. Conversely, 1 horse power = 0.746 kilowatt. Comparing with units of *mechanical work*, it is evident from the above that 1 kilowatt hour = 1.3405 horse-power hour; and that 1 horse-power hour = 0.746 kilowatt hour. Comparing with units of *thermal work*, $1 \text{ kilowatt hour} = \frac{265.428}{778} = 341.17 \text{ thermal units}$; and conversely, 1 thermal unit (B. T. U.) = 0.002931 kilowatt hour (= 2.931 watt hours), or 10,000 B. T. U. (= amount of heat that may be assumed to be generated in a boiler from the combustion of 1 lb. of coal) = 29.31 kilowatt hours.

A Kilowatt is an "electric horse-power."

Problem 1 (Steam-Electric).—What power can be expected from a dynamo (generator) operated by a steam engine, with a consumption of 500 lbs. of coal per hour (assuming that each 100 lbs. generates 1,000,000 B. T. U. in the steam); the engine having an efficiency of 10 per cent, and the dynamo 93 per cent?

Solution.—From the above we have $1,000,000 \times 5 \times 0.002931 \times 0.10 \times 0.93 = 1362.92 \text{ kilowatts (or 1827 horse-power)}$. Ans.

Problem 2 (Hydro-Electric).—A direct-connected dynamo is run by an impulse water-wheel under a static head of 200 feet, and using water at the rate of 48 cubic feet per minute. Assuming the loss of head in the pipe line (from the storage to the wheel) to be 20 ft., the efficiency of the wheel 85 per cent., and the generator 93 per cent*; what power will be furnished to the line?

Solution.—Theoretically, the water power = $200 \times 48 \times 62.5 = 600,000 \text{ ft.-lbs. per minute, or } 18.182 \text{ horse-power}$. The efficiency of the pipe line is $\frac{200 - 20}{200}$ or 90 per cent. Hence, power delivered to line is $18.182 \times 0.90 \times 0.85 \times 0.93 \times 0.746 = 9.65 \text{ kilowatts (or } 18.182 \times 0.90 \times 0.85 \times 0.93 = 12.94 \text{ horse-power)}$.

What are Electrical Machines?—Electrical machines are machines for generating, controlling, transforming or converting electrical energy.

Dynamos are machines for converting mechanical- into electrical power, that is, they generate electricity and hence the name "generator." An

* Generators are constructed with efficiencies as high as 96 per cent.

electric "motor" differs from a generator in that it converts electrical into mechanical power—a reverse operation. The essential principles of the motor are those of the dynamo. Dynamos and motors may be either alternate-current or continuous-current machines.

Transformers are machines placed at either end (or at any point) of a transmission line to change the potential of the current. For instance, if it is desired to carry the current over the line at a higher potential than it is practicable for the dynamos to generate, the *step-up* transformer is used at the power-house end of the line; while at the delivery end the *step-down* transformer is installed. Transformers are either air-cooled, water-cooled or oil-cooled. In the latter case the whole transformer is placed in oil which penetrates the pores and insulates the wires.

Converters, called rotary converters, are machines for converting alternate currents to direct currents, or vice versa; or they may be used for changing the voltage of continuous currents, or changing the voltage, phase or frequency of alternating currents.

Boosters are machines inserted at distant points in the line, as at the outer ends of street-railway circuits, to compensate the drop in voltage in direct-current mains. A booster is a combination motor-generator or motor-dynamo or series motor driving an armature placed as a shunt across the mains. It can be arranged to either raise or lower the voltage, being generally used for the former purpose.

Principles of Electricity and Magnetism.—Before proceeding immediately with the discussion of electrical machines let us first consider the question—

What is Electricity?—Scientists are pretty well agreed at the present day that *electricity* and *magnetism*, closely associated, are due to certain states of disturbance in the universal substance (?) called *ether*, which pervades all space and gross matter. Other states of disturbance are called *light* and *heat*. Indeed, by some it is considered not improbable that gross matter itself is ethereal and electrical by nature, thus accounting for the universal law of *gravitation*. It is not unlikely that the determination of the exact nature of either of the above phenomena will reveal the nature of all the others.

Ether, as a substance, necessarily has mass, and it has been estimated, from experiments made on the energy of waves of light, that a volume of ether the size of the earth will weigh as much as 4 cubic feet of water. It is considered to be perfectly elastic and in a continual state of unrest. It is not difficult to imagine that it may be a fourth state of "matter" in the rising gradation from solid, liquid and gaseous to the ethereal; the first three constituting *gross* matter, with definite chemical composition, and the last, radiant or transcendental matter, whose composition is as yet unknown.

Ether Waves vary greatly in length according to the phenomena produced. The shortest wave lengths of which we have any knowledge (by the action of the photographic plate) number about 300,000,000,000,000 vibrations per second (in a length of 186,500 miles or 11,816,640,000 inches) equivalent to less than one 25-millionth of an inch in length. These waves are able to penetrate paper, wood and sheets of metal as ordinary light waves penetrate glass. They are far beyond the range of the eye as are also, but to a much less degree, the ultra-violet rays, estimated to be about one 70-thousandth of an inch in length. As the waves become longer they fall within the visible spectrum, the violet rays being about one 60-thousandth of an inch, and the red rays (the longest rays visible), about one 37-thousandth of an inch in length. Those rays from the violet to the red (including all the known colors) have the peculiar property, by virtue of the transverse vibrations, of acting on the retina of the eye (consisting of minute protuberances which are set in vibration) and producing the sensation of light. As the waves increase in length we get first the heat wave and finally the electric wave, the latter being the longest.

Electricity and Magnetism are mutually related, and it is owing to these peculiar properties or phenomena that we are enabled to generate electricity and use it, commercially.

Magnetic Field.—When a current of electricity flows "through" a wire in a closed circuit it *induces* around the wire a magnetic "field." Let Fig. 1 represent a section of such a circuit with the copper wire piercing a

small sheet of paper, and the current flowing downward as shown by the vertical arrows. If, now, a few iron filings are sprinkled on the paper and the paper tapped gently, it will be found that the filings will arrange themselves in concentric rings as shown. If, further, a compass is brought close to the wire, the needle will be found to swing in a position tangent to the filing rings, with the *N* pole pointing in the direction of the arrows shown on the paper. Upon reversal of the current through the wire the magnetic needle will also reverse in direction by 180° . We may say, then, that the "lines of force" in the induced magnetic field are right-handed or clockwise when looking in the direction of the circuit. The rapid reversal of the electric current in the circuit, producing what is called the alternating current (as against the continuous or direct current) induces, therefore, an alternating magnetic field. The "strength" of the field is directly proportional to the current strength, and decreases with the distance from the wire.

Fig. 1.

The Electro-Magnet.—The principle of the electro-magnet is based on the magnetic field, explained above. *AB*, in each of the following Figs., is the primary circuit with the current flowing in the direction *AB*, as shown

Fig. 2.

Fig. 3.

Fig. 4.

Fig. 5.

Fig. 6.

by the arrows. Now we have seen, Fig. 1, that when a current of electricity flows through the primary circuit, lines of force are set up, around the conductor, in a clock-wise or cock-screw direction. If the iron filings are replaced by a circular ring of metal, as in Fig. 2, lines of electro-magnetic force will be *induced* in the ring in the direction shown by the arrows. Fig. 3 shows the same phenomenon, but with the magnetic circuit forming merely a loop around the primary. Fig. 4 shows the circuit of the loop "broken" thus forming a primitive horse-shoe magnet, the + and - ends of which attract each other, tending to draw together and "close" the circuit. Figs. 5 and 6 show that two *parallel conductors attract* each other when the currents flow in the same direction, and *repel* each other when the currents flow in opposite directions. By reversing the direction of the current in *AB*, the direction of the magnetic circuit in Figs. 2 and 3 will also be reversed, and in Fig. 4 the poles of the magnet will change from + to -, and from - to +. Repulsion will now take place between the parallel conductors in Fig. 5, and attraction in Fig. 6, assuming that the currents *ab* remain unchanged. Now assume *ab*, Figs. 5 and 6, to be uncharged from any secondary batteries, and assume the current in the primary conductor to flow in the direction *AB*; then, if the current is continuous there will be no induced current in *ab*, but if it is alternating there will be, during the time the current is increasing in strength or "setting up of the field," a tendency toward generating currents in *ab*. Such currents are called *induced currents*, and the general phenomenon is termed *Induction*.

Fig. 7.

Fig. 8.

Induction can, perhaps, best be explained by the theory that magnetism is merely electricity in a whirl, rotating about a conductor in the surround-

ing ether. It is greatly assisted and intensified by the use of a soft-iron core around which a certain number of turns of each circuit is wound. Fig. 7 illustrates an induction coil or Transformer consisting essentially of a core around which is wound x turns of the primary circuit, $P-P$, and then y turns of the secondary circuit, $S-S$. From the number of turns of wire, we have, electro-motive force in $S-S = \frac{y}{x} \times$ (electro-motive

force in $P-P$), therefore, by increasing the ratio of turns in secondary coil to those in primary coil the E. M. F.* is increased.

Faraday's ring, Fig. 8, consisted of a circular core with the primary and secondary coils on either side. The arrows on the ring indicate the direction of the electro-magnetic stresses. An alternating current in the primary coil P (Figs. 7 and 8) generates an alternating current in the secondary coil S ; and again, S may be used as the primary coil and P as the secondary coil.

The Horse-Shoe Magnet is commonly made by bending a piece of steel in the form of a horse-shoe as shown in Fig. 9, winding it with fine copper wire (either partially as shown by the double lines or completely around the loop as shown by the single lines) and passing a current of electricity through the wire as shown by the arrows, "breaking" (shutting off) the current occasionally. The wire is now unwound and it is found that the bar of steel has become a *permanent* magnet, capable of attracting magnetic substances as iron or steel. If *soft iron* is used for the "field core" instead of steel it will retain the properties of a magnet only when the current of electricity is "exciting" the field. Such a magnet is called an *electro-magnet*. Note that the armature A when placed within the "influence" of the magnetic poles of the field core is attracted by the latter, that is, the armature tends to "close" the magnetic circuit. The telegraph "sounder" is founded on this principle.

Fig. 9.

Electro-Magnets are made in various forms, depending on the kind of work they are intended to do. We stated in the last paragraph that the armature A (Fig. 9) is attracted by the poles of the field core and tends to "close" the magnetic circuit. This is only partly true. As a matter of fact the magnetic circuit in Fig. 9 is already complete without the presence of the armature, but it is comparatively feeble and grasps the armature to form a more "permeable" path for its circuit than the air offers, much the same as a man uses a plank to cross a small stream instead of wading. The "Theory of least work" applies to all electric and magnetic phenomena as it does to mechanics. It is simply another name for the "Conservation of Energy."

Principle of the Alternate-Current Dynamo.—A simple form of generator is illustrated in Fig. 10. The magnetic "field" between N and S is induced by either a permanent magnet or an electro-magnet (see Fig. 9). Between the poles of the magnet is shown a loop of copper wire which may be made to revolve on an axis ab ; we have also to imagine that there are *lines*, tubes, or cylinders, of *force* stretching between the N and S poles of the magnet. Now when the copper loop is revolved, say right-handed, it cuts these lines of force and *alternate* currents of electricity are generated in the copper wire circuit, the N pole inducing a current in the nearest parallel portion of the loop, toward a , and the S pole toward b . Both currents therefore flow around the coil in the *same* direction for each half turn, and then reverse. It is to be noted, however, that the comparative strength of the current depends on the number of lines of force cut per second, that is, the rate of transverse cutting of the lines of force. By referring to the end view in Fig. 10 it will be seen that this rate is proportional to $\sin \alpha$; when $\alpha = 90^\circ$ the copper loop is cutting the lines of force at a maximum rate, unity; when $\alpha = 45^\circ$ the rate is 0.707; when $\alpha = 0^\circ$ no lines

Fig. 10.

* Electro-motive force is voltage or difference of potential. E. M. F. is increased at the expense of current, where the power remains the same.

of force are being cut and hence no current is flowing in the circuit. This last position is also the point of alternation of the current, which continues in one direction for every *half* revolution of the coil and then reverses.

The electricity generated in the revolving armature, for one-half turn, is conducted to the revolving "collecting" ring, *R* (Fig. 11), thence by the fixed "brush" *B* to the line *L*, where it is made to perform useful work such as running a motor, *M*. Passing through *M* it returns to the armature by way of *L'*, *B'* and *R'*, thus completing the circuit. For the next half turn it reverses in direction, thus alternating. If the circuit is disconnected or broken at any point no power can be furnished. The earth is sometimes used for the return current as in telegraph circuits. In the case of electric railways the rails are used. If they are "bonded" the "resistance" is greatly lessened.

Fig. 11.

Now instead of having a "revolving armature" composed of only *one* copper wire loop as shown in Fig. 10, we may increase the current output of the machine by using a cylindrical armature composed of a *large number* of loops; also, the field-magnet with only two poles may be increased so as to contain a large number of pairs of poles.

The magnetic field of large commercial alternate-current dynamos is generally maintained by small constant-current generators called "exciters." One exciter will answer for one or more of the large alternators, and being continuous-current machines they are self-exciting (see page 1384).

CLASSIFICATION OF ALTERNATE-CURRENT DYNAMOS.

(See also page 1384.)

A.—With respect to stationary and moving parts:

- (a) Stationary field magnets and rotating armatures;
- (b) Stationary armatures and rotating field-magnets;
- (c) Stationary field-magnets and armatures, and revolving inductors. (Not common. Ex.: Stanley-Kelly inductor alternator.)

B.—With respect to number of field-magnet poles:

- (a) 2-pole (bipolar), 4-pole, 6-pole, 8-pole machines;
- (b) Multipolar machines include all above the bipolar. (Multipolar machines, with many poles, used for high power.)

C.—With respect to form of armature:

- (a) Ring armature;
- (b) Drum armature;
- (c) Disk armature (core disks, sunk wound, are preferred to thin disks for high power machines, because of strength);
- (d) Pole armature.

D.—With respect to armature coils:

- | | | | |
|------------------|----------|-----------------|----------------------------|
| (a) Open coil; | } Also { | (A) In parallel | { For increase of current. |
| (b) Closed coil; | | (B) In series | |

E.—With respect to armature windings:

- (a) Spiral or ring winding (ring armatures);
 - (b) Lap winding
 - (c) Wave winding
 - (d) Sunk winding.
- } drum and disk armatures;

F.—With respect to field-magnet windings:

- (a) Spiral winding;
 - (b) Lap winding;
 - (c) Wave winding;
 - (d) Sunk winding.
- } Also { (A) In parallel.
(B) In series.

* Collecting rings or simply collectors are used on alternate-current machines, while "commutators" (see page 1384) are used on continuous-current dynamos.

G.—With respect to phase of machine:

- (a) Single-phase, 2-phase, 3-phase machines;
- (b) Polyphase machines include all above 2-phase.

A single-phase alternator is one in which the currents act in unison, rising and falling together; while in a polyphase alternator the coils are arranged so that the impulses are produced closer together, thereby maintaining a more uniform electro-motive force. 2-phase and 3-phase alternators are the most common.

Principle of the Continuous-Current Dynamo.—Many of the principles of the alternate-current dynamos, just described, apply equally as well to the continuous-current machines. We have the field-magnet and also the armature; but instead of using collector rings or collectors as for the alternators, we use *commutators*, which deliver to the external circuit a *continuous current*, that is, a current in one direction through the external circuit.

Fig. 12 shows a simple, two-part commutator, *K* and *K'*, joining the ends of a single-loop armature revolving between the poles of a magnet on the axis *a b*, and delivering current to the brush *B*. Note that the brushes *B* and *B'* are fixed, and as the commutator revolves (with the armature) the *K*-part and the *K'*-part alternate in delivering current to *B*, and hence it always flows through the external circuit, from *B* to *B'*, in one direction.

Fig. 12.

Continuous-current dynamos are made with two, four, six or eight poles, the two-pole machines being the most common. The armature winding, however, is very complex. Instead of one loop, as in Fig. 12 there are many loops; and the commutator, instead of being composed of two shells or bars, as above, may be composed of many bars (see Fig. 13). Hard-drawn copper is best for the commutator bars, and also for the brushes.* All field and armature windings, as well as commutator bars, should be insulated. The latter are insulated with mica.

CLASSIFICATION OF CONTINUOUS-CURRENT DYNAMOS.

(See also page 1383.)

I.—With respect to excitation of field-magnets:

- (a) *Separately-excited* dynamo (Fig. 13), using a separate (small) dynamo as an exciter;
- (b) *Series* dynamo (Fig. 14), using the full current of the external circuit as an exciter;
- (c) *Shunt* dynamo (Fig. 15), using a small fraction of the external circuit (by a shunt circuit of thin wire) to excite the field;
- (d) *Compound* dynamo (Fig. 16), using both shunt coils and series coils to excite the field.

Fig. 13.

Fig. 14.

Fig. 15.

Fig. 16.

Note.—In addition to the above we have also the *Magneto* dynamo, in which the field-magnets are permanent steel magnets; and the *Separate-coil* dynamo, in which the armature is wound with a separate coil to act as an exciter.

* Carbon brushes are used for motors.

II.—With respect to other characteristics see classification of alternate-current dynamos, page 1383, with the following comments for direct-current machines:

- A.—(a) Stationary field-magnets and rotating armatures, is the prevailing type.
- B.—Bipolar machines are generally used; although 4-, 6-, and 8-pole machines are not uncommon. There is another type, namely, the homopolar (unipolar or 1-pole) machine which is being developed with more or less success.
- C.—(b) Drum armatures are the most efficient and are generally used where high potential is required. Ring armatures give lower E. M. F. and less current for the same number of revolutions.
- D.—(b) Closed-coil armatures, generally speaking, give greater commercial efficiency than open-coil machines; but the latter (whether of the ring or drum type) are better adapted to high electro-motive forces because of the methods of insulation of commutator bars. The Brush and the Thomson-Houston open-coil dynamos are especially adapted to electric lighting, and it may be said that they practically monopolize the field for this purpose.
- E.—(b) Lap winding is the most frequently used.
- F.—Wave winding has certain disadvantages and has not come into general use.
- G.—Phase applies to alternate-current machines.

Electric Transmission of Power.—Important considerations come up in connection with the projection of any power plant, especially for long-distance transmission; and usually the combined efforts of the civil-, electrical-, mechanical- and hydraulic engineer are required for its successful installation.

Uses of Electric Power.—Electric power can be used for every purpose for which power is required. Its practical utility as compared with the direct use of steam and water power, from which it is derived mainly, lies in the economic, convenient and sanitary distribution from a central station, where it can be generated economically.

Sources of Electric Power.—Entropy, in thermodynamics, has been defined by some scientists as the "available" energy in any system, while others define it as the "non-available" energy in any system. Electricity may similarly be defined. It is only a question of constructing our machines so that the kind of energy which is usually lost may be increased, captured and turned into useful work at some distant point. The dynamo, the transmission line and the motor are specially designed to accomplish this result economically.

The primary source of all electric- or other power is probably electricity itself. The immediate source appears to us in the forms of chemical and physical actions, the latter through the agencies of heat and gravitation, acting on gross matter, either solid, liquid or gaseous. Thus, we get the battery, thermopile, steam-engine, so-called heat engine (including the gas engine), and the water wheel. No method has yet been discovered by which electricity can be generated directly from heat on a large commercial scale. The present indirect use of heat of fuel means a loss of 90 per cent or more of heat energy.

For large electric plants the steam engine and the water wheel only can be considered as prime sources of power. The turbine wheel is best adapted to low heads, and the impulse (bucket) wheel for high heads. The exact dividing line between "low" and "high" heads is not well marked. They both overlap the 100-ft. head, sometimes to a considerable extent.

Steam and Water-Power Compared.—The cost of fuel on the one hand, and the length of transmission, on the other, are prime factors in the comparison. For example, the author has in mind a proposed change from steam- to water power in the generation of electric power for a street railway, demanding about 3000 horse-power. The fuel for the steam plant was very cheap, consisting of saw-dust and slabs automatically fed from a neighboring saw-mill. This could have been supplanted by a transmission

30 miles long, and the installation of a power house with impulse wheel operating under a 600-ft. head. The low cost of fuel, however, favored the steam plant. With coal as a fuel the water-power proposition would have been cheaper.

Alternating- vs. Continuous Current.—Although alternate-current motors may be used to convert alternate-current directly into mechanical work, yet, owing to certain disadvantages they have not come into general use. Even in lighting, the arc lamp on a continuous current circuit gives a better illumination, and it is also free from the humming sound produced when the lamps are on alternate-current circuits. With the incandescent lamp, however, there is less contrast in candle power. But there are other considerations which sometimes outweigh the above, and we find both the alternating- and continuous current in distributing systems for motive power and lighting.

The electric transmission of power for *moderate distances* is almost always by *direct current*. This system involves line construction of the most simple character, namely, two lines of wire. The current is generated at the power station by continuous-current dynamos. Each machine may be designed to yield a voltage up to 2500 or even 4000 volts, although the latter is uncommon. In order to secure a high voltage in transmission (which means a saving in copper or aluminum wire) the dynamos are placed in "series." Thus, ten dynamos in series, each generating current at say 2000 volts, will deliver about $10 \times 2000 = 20,000$ volts to the line. At the distributing end of the line the total voltage of the motors receiving the energy at any one time must be equal to that of the generators, minus the "drop" in volts on the line. Continuous-current transmission may operate in three ways:

- (1) Constant voltage and variable current;
- (2) Constant current and variable voltage;
- (3) Variable voltage and variable current.

Long-Distance Transmission may be accomplished by either alternating or continuous current. In Europe the latter has many adherents, while in America "long-distance" is almost synonymous with "alternate-current" transmission. The "first cost" of installation, however, is usually greater for alternate-current transmission.

Alternate-current transmission is carried out with three-phase three-wire, two-phase four-wire or single-phase two-wire circuits, the first named greatly predominating, and the last being seldom used. The number of wires varies from three, the lowest, to say six, a maximum per pole in good practice. High voltage for alternate-current transmission can be obtained only by step-up transformers installed at the power station because alternators cannot be connected up in series for higher voltage as can continuous-current dynamos. They may be designed, however, to deliver, individually, current at a much higher voltage, namely, up to 15,000 and possibly 20,000 volts. The step-down transformers at the sub-stations need not be the same in number as the step-up transformers at the generating stations. Transformers can be wound for any rating of voltage of primary to secondary coils, but there are certain economic ratios related more or less to generator capacity. Static transformers are often used to change alternating current from 3-phase to 2-phase, and vice versa.

The Transmission Line.—The material for line conductors has settled down to a choice mainly between aluminum and copper. In fact, the former metal has recently been used in many of the largest installations.* From an economic standpoint, considering the electrical and mechanical properties of the two metals, they possess equal merit when the price of aluminum wire, per pound, is about 2 to 2.1 times the price of copper; or when the price of copper wire is about 48 to 50 per cent of the price of aluminum. Hence, with copper at 22 cents per pound, aluminum would be selected if under 45 cents per pound†. Aluminum *cable* is substituted for *wire* if the size called for is large, say larger than No. 1 B. & S. gage, and sometimes even for smaller sizes. The cables are made up of wires ranging in size usually from 6 to 9 B. & S. gage, sometimes larger. Seven strands per cable are common, and as high as 37 have been used.

* The use of aluminum has not been confined to main transmission lines. It is being used also in distributing power to sub-stations of electric railways, and for city distribution of both light and power. † See page 496.

The Size of Conductors which it is advisable to use in a transmission line cannot be determined by any simple rule. As a broad proposition it may be stated that the whole power plant, from reservoir (or other source of power) to distribution, should be so designed that, when furnishing the required power, it is found that *no slight increase or decrease of power could have been effected more economically at one part of the plant than at another.* But there are many practical considerations. The "required" power varies from hour to hour of the day, from season to season of the year, and also from year to year. We may perhaps assume the "required" power to be the maximum or "peak" load, either present or prospective; or we may assume it to range somewhere between the peak load and the average load, generally near the former and a little below it. If storage batteries are installed to take care of the peak load the "required" power for the line may be lowered accordingly, but if this is not done the peak loads must of course be carried by bringing into action additional (reserved) units at the power house. Such units consist each of say a water wheel (or an engine) with the connected generator or generators.

Let us assume that the "required" power, for which the transmission line is to be designed, has been determined as x watts ($= \frac{x}{1000}$ kilowatts) $= C$ (amperes) $\times E$ (volts). Now we have as limiting guides, in determining the size of the wire, the following, namely, (1) that it is inadvisable to use a single copper wire of a size less than No. 4 B. & S. gage, for reasons of strength and stiffness; (2) a tentative calculation of the line wire should show a loss of say from 5 to 10 per cent of the "required" power delivered to the line, less for short- and perhaps greater for long transmission. Then by applying the above rule (in italics) see whether or not an incremental increase or decrease of power can be effected in the line (by changing the size of wire) at less cost than could be effected at the generator station and at other points.

TRANSMISSION LINE PROBLEMS.

Problem 1.—What size of copper wire is required in a 25-mile continuous-current transmission receiving 3,600 kilowatts at 30,000 volts pressure, allowing a "drop" in volts of 10 per cent on the line?

Solution.—3,600 kilowatts = 3,600,000 watts, hence the current in amperes = 120 amperes. With a 10 per cent drop in voltage the line loss = $30,000 \times 0.10 = 3,000$ volts. Now applying Ohm's law ($C = \frac{E}{R}$) we have,

resistance in ohms = $\frac{E}{C} = \frac{3000}{120} = 25$ ohms. As this resistance is distributed

over 25×2 (2-wire circuit) = 50 miles, the resistance per mile = $\frac{25}{50} = 0.50$

ohm, which, from table 1, page 1389 corresponds to a No. 0, B. & S. gage, copper wire. If aluminum is used it would require a No. 000. In general, there is a difference of two numbers between copper and aluminum wire for the same resistance. Note in the above that E = the difference of potential between the two ends of the line. Also that the resistance is taken at 75° F., and that the resistance increases with increase of temperature (see Table 1, page 1389).

The above method of solution applies to all continuous-current two-wire circuits, and can be used as well to find the weight of wire per unit of length, or the area in circular mils. It is a question simply of using different tables after the resistance has been obtained. Thus, a resistance of 0.5 ohm per mile is equal to 0.0947 ohm per 1,000 feet, or 10,560 feet per ohm; equivalent to 110,000 circular mils, or 3 feet per pound of wire, at 75° F.

For alternating-current circuits the above method of solution may be used by noting the following: (1) The "virtual volts" and "virtual amperes" of the alternating current* (and these are what are commonly meant), such as are recorded by volt- and ampere meters, must be used in the calculations. (2) There are two additional sources of loss in alternate-current lines that do not appear with the continuous current, namely, *inductance*

(Continued on page 1392.)

* In alternating currents the maximum volts and amperes rise to about 1.414 times the virtual, alternating between that and zero, the virtual being about 0.707 times the maximum.

1.—COPPER WIRE TABLE OF THE—

(Supplement to Trans. of A. I. E. E., Oct., 1893.)

The data from which this table has been computed are as follows: Matthiessen's standard resistivity, Matthiessen's temperature coefficient, specific gravity of copper = 8.89. Resistance in terms of the international ohm.

Matthiessen's standard 1 meter-gram of hard drawn copper = 0.1460 B. A. U. at 0° C. Ratio of resistivity, hard or soft copper, 1.0226.

Matthiessen's standard 1 meter-gram of soft drawn copper = 0.14365 B. A. U. at 0° C. 1 B. A. U. = 0.9866 international ohm.

Matthiessen's standard 1 meter-gram of soft drawn copper = 9.141779 international ohms at 0° C.

Temperature coefficients of resistance* for 20° C., 50° C., and 80° C. are
(See Opposite Page for Areas in Square Mils.)

—AM. INST. OF ELECTRICAL ENGINEERS.

1.07968, 1.20625, and 1.33681, respectively. 1 foot = 0.3048028 meter, 1 pound = 453.59256 grams.

Although the entries in the table are carried to the fourth significant digit, the computations have been carried to at least five figures. The last digit is therefore correct to within half a unit, representing an arithmetical degree of accuracy of at least one part in two thousand. The diameters of the B. & S. or A. W. G. wires are obtained from the geometrical series, in which No. 0000 = 0.46 inch and No. 36 = 0.005 inch, the nearest fourth significant digit being retained in the areas and diameters so deduced.

It is to be observed that while Matthiessen's standard of resistivity may be permanently recognized, the temperature coefficient of its variation which he introduced, and which is here used, may in future undergo slight revision.

(See Opposite Page for Areas in Circular Mils.)

find area in square inches, divide by 1,000,000.

and *impedance*. The former may be assumed to be no greater than the "drop" in volts on the line (and from that down to about one-third of the amount), while the latter is usually so small as to be practically negligible, say 5 per cent of the inductance. Hence from 5 to 10 per cent may be added for losses in alternate-current circuits over those for continuous; in other words the areas of the wires may be increased by this amount. (3) In a single-phase two-wire circuit the size of wires is the same as for continuous current *plus* 5 to 10 per cent for inductance. (4) In a two-phase four-wire circuit the area of each wire is one-half that for the continuous current circuit *plus* 5 to 10 per cent for inductance; that is, the same *weight* of wire is required as for the single-phase two-wire alternating circuit. (5) In the three-phase three-wire circuit the area of each wire is one-half that for the continuous current circuit *plus* 5 to 10 per cent for inductance; that is, only three-fourths the *weight* of wire is required as for the 1-phase 2-wire, and 2-phase 4-wire, circuits.

Problem 2.—In solving Problem 1 we find that the size of copper wire required is about 110,000 circular mills in area, corresponding to about No. 0 B. & S. gage. Now, from the foregoing discussion, what sizes of wire would probably be installed for the three types of alternating circuits? And what would be the theoretic relative weights of *total amount of copper* in the four systems?

Continuous current	2-wire;	each 110,000 circ. mills;	total weight, 1.00
Alternating Current	1-phase 2-wire;	" 120,000 "	" 1.09
	2-phase 4-wire;	" 60,000 "	" 1.09
	3-phase 3-wire;	" 60,000 "	" 0.82

The 3-phase 3-wire system is the most commonly used.

“NATIONAL ELECTRIC CODE.”

**Rules and Requirements of the National Board of Fire Underwriters
for the Installation of Wiring and Apparatus (for Light, Heat
and Power) as Recommended by the Underwriters’
National Electric Association.
Edition of 1907.**

The National Electric Code (originally drawn in 1897) is the result of the united efforts of the various electrical, architectural, insurance and other allied interests which, through the National Conference on Standard Electrical Rules, composed of delegates from various national associations, unanimously voted to recommend it to their respective associations for approval or adoption.

The following is a list of the associations composing the National Conference on Standard Electrical Rules:—American Institute of Architects, American Institute of Electrical Engineers, American Society of Mechanical Engineers, American Institute of Mining Engineers, American Street and Interurban Railway Association, Associated Factory Mutual Fire Ins. Co’s., Association of Edison Illuminating Companies, International Association of Municipal Electricians, National Board of Fire Underwriters, National Electric Light Association, National Electric Contractors’ Association, National Electric Inspectors’ Association, Underwriters’ National Electric Association.

GENERAL PLAN GOVERNING THE ARRANGEMENT OF RULES.*

Class A.—Stations and Dynamo Rooms. Includes Central Stations; Dynamo, Motor, and Storage-Battery Rooms; Transformer Substations, etc. Rules 1 to 11.

Class B.—Outside Work, all systems and voltages. Rules 12 to 13A.

Class C.—Inside Work. Rules 14 to 39. Subdivided as follows:
General Rules, all systems and voltages. Rules 14 to 17.
Constant-Current Systems. Rules 18 to 20.
Constant-Potential Systems:—

General Rules, all voltages. Rules 21 to 23.

Low-Potential Systems, 550 volts or less. Rules 24 to 34.

High-Potential Systems, 550 to 3500 volts. Rules 35 to 37.

Extra-High-Potential Systems, over 3500 volts. Rules 38 to 39.

Class D.—Fittings, Materials, and Details of Construction, all systems and voltages. Rules 40 to 63.

Class E.—Miscellaneous. Rules 64 to 67.

Class F.—Marine Work. Rules 68 to 83.

* **General Suggestions.**—In all electric work, conductors, however well insulated, should always be treated as bare to the end that under no conditions, existing or likely to exist, can a ground or short circuit occur, and so that all leakage from conductor to conductor, or between conductor and ground, may be reduced to a minimum.

In all wiring, special attention must be paid to the mechanical execution of the work. Careful and neat running, connecting, soldering, taping of conductors, and securing and attaching of fittings, are specially conducive to security and efficiency, and will be strongly insisted on.

In laying out an installation, except for constant current systems, every reasonable effort should be made to secure distribution centers located in easily accessible places, at which points the cut-outs and switches controlling the several branch circuits can be grouped for convenience and safety of operation. The load should be divided as evenly as possible among the branches, and all complicated and unnecessary wiring avoided.

The use of wire-ways for rendering concealed wiring permanently accessible is most heartily endorsed and recommended; and this method of accessible concealed construction is advised for general use.

Architects are urged, when drawing plans and specifications, to make provision for the channeling and pocketing of buildings for electric light or power wires, and also for telephone, district messenger and other signaling system wiring.

Class A.—STATIONS AND DYNAMO ROOMS.

INCLUDES CENTRAL STATIONS, DYNAMO, MOTOR AND STORAGE-BATTERY ROOMS, TRANSFORMER, SUB-STATIONS, ETC.

1. Generators.—a. Must be located in a dry place.

It is recommended that water-proof covers be provided, which may be used in case of emergency.

b. Must never be placed in a room where any hazardous process is carried on, nor in places where they would be exposed to inflammable gases or flyings of combustible materials.

c. Must, when operating at a potential in excess of 550 volts, have their base frames permanently and effectively grounded.

Must, when operating at a potential of 550 volts or less, be thoroughly insulated from the ground wherever feasible. Wooden base frames used for this purpose, and wooden floors which are depended upon for insulation where, for any reason, it is necessary to omit the base frames, must be kept filled to prevent absorption of moisture, and must be kept clean and dry.

Where frame insulation is impracticable, the Inspection Department having jurisdiction may, in writing, permit its omission, in which case the frame must be permanently and effectively grounded.

A high potential machine should be surrounded by an insulated platform. This may be made of wood, mounted on insulating supports, and so arranged that a man must always stand upon it in order to touch any part of the machine.

In case of a machine having an insulated frame, if there is trouble from static electricity due to belt friction, it should be overcome by placing near the belt a metallic comb connected with the earth, or by grounding the frame through a resistance of not less than 300,000 ohms.

d. Constant potential generators, except alternating current machines and their exciters, must be protected from excessive current by safety fuses or equivalent devices of *approved* design.

For two-wire, direct-current generators, single pole protection will be considered as satisfying the above rule, provided the safety device is located in the lead not connected to the series winding. When supplying three-wire systems, the generators should be so arranged that these protective devices will come in the outside leads.

For three-wire, direct-current generators, a safety device must be placed in each armature, direct-current lead, or a double pole, double trip circuit breaker in each outside generator lead and corresponding equalizer connection.

In general, generators should preferably have no exposed live parts and the leads should be well insulated and thoroughly protected against mechanical injury. This protection of the bare live parts against accidental contact would apply also to any exposed, uninsulated conductors outside of the generator and not on the switchboard unless their potential is practically that of the ground.

Where the needs of the service make the above requirements impracticable, the Inspection Department having jurisdiction may, in writing, modify them.

e. Must each be provided with a name-plate, giving the maker's name, the capacity in volts and amperes, and the normal speed in revolutions per minute.

f. Terminal blocks when used on generators must be made of *approved* non-combustible, non-absorptive, insulating material, such as slate, marble or porcelain.

2. Conductors.—From generators to switchboards, rheostats or other instruments, and thence to outside lines:—**a. Must be in plain sight or readily accessible.**

Wires from generator to switchboard may, however, be placed in a conduit in the brick or cement pier on which the generator stands, provided that proper precautions are taken to protect them against moisture and to thoroughly insulate them from the pier. If lead-covered cable is used, no further protection will be required, but it should not be allowed to rest upon sharp edges which in time might cut into the lead sheath, especially if the cables were liable to vibration. A smooth runway is desired. If iron conduit is provided, double braided rubber-covered wire (see No. 47) will be satisfactory.

b. Must have an *approved* insulating covering as called for by rules in Class "C" for similar work, except that in central stations, on exposed circuits, the wire which is used must have a heavy braided, non-combustible outer covering.

Bus bars may be made of bare metal.

Rubber insulations ignite easily and burn freely. Where a number of wires are brought close together, as is generally the case in dynamo rooms, especially about the

switchboard, it is therefore necessary to surround this inflammable material with a tight, non-combustible outer cover. If this is not done, a fire once started at this point would spread rapidly along the wires, producing intense heat and a dense smoke. Where the wires have such a covering and are well insulated and supported, using only non-combustible materials, it is believed that no appreciable fire hazard exists, even with a large group of wires.

Flame proofing should be stripped back on all cables a sufficient amount to give the necessary insulation distances for the voltage of the circuit on which the cable is used. The stripping back of the flame proofing is necessary on account of the poor insulating qualities of the flame proofing material now available. Flame proofing may be omitted where satisfactory fire-proofing is accomplished by other means, such as compartments, etc.

c. Must be kept so rigidly in place that they cannot come in contact.

d. Must in all other respects be installed with the same precautions as required by rules in Class "C" for wires carrying a current of the same volume and potential.

e. In wiring switchboards, the ground detector, voltmeter, pilot lights and potential transformers must be connected to a circuit of not less than No. 14 B. & S. gage wire that is protected by an *approved* fuse, this circuit is not to carry over 660 watts.

For the protection of instruments and pilot lights on switchboards, *approved* N. E. Code Standard Enclosed Fuses are preferred, but *approved* enclosed fuses of other designs of not over two (2) amperes capacity, may be used.

Voltmeter switches having concealed connections must be plainly marked, showing connections made.

3 Switchboards.—a. Must be so placed as to reduce to a minimum the danger of communicating fire to adjacent combustible material.

Special attention is called to the fact that switchboards should not be built down to the floor, nor up to the ceiling. A space of at least ten or twelve inches should be left between the floor and the board, except when the floor about the switchboard is of concrete or other fireproof construction, and a space of three feet, if possible, between the ceiling and the board, in order to prevent fire from communicating from the switchboard to the floor or ceiling, and also to prevent the forming of a partially concealed space very liable to be used for storage of rubbish and oily waste.

b. Must be made of non-combustible material or of hardwood in skeleton form, filled to prevent absorption of moisture.

If wood is used all wires and all current carrying parts of the apparatus on the switchboard must be separated therefrom by non-combustible, non-absorptive insulating material.

c. Must be accessible from all sides when the connections are on the back, but may be placed against a brick or stone wall when the wiring is entirely on the face.

If the wiring is on the back, there should be a clear space of at least eighteen inches between the wall and the apparatus on the board, and even if the wiring is entirely on the face, it is much better to have the board set out from the wall. The space back of the board should not be closed in, except by grating or netting either at the sides, top or bottom, as such an enclosure is almost sure to be used as a closet for clothing or for the storage of oil cans, rubbish, etc. An open space is much more likely to be kept clean, and is more convenient for making repairs, examinations, etc.

d. Must be kept free from moisture.

e. On switchboards the distances between bare live parts of opposite polarity must be made as great as practicable, and must not be less than those given for tablet-boards (see No. 63 A).

4. Resistance Boxes and Equalizers.—(For construction rules, see No. 60.) a. Must be placed on a switchboard, or if not thereon, at a distance of at least one foot from combustible material, or separated therefrom by a non-combustible, non-absorptive insulating material such as slate or marble.

This will require the use of a slab or panel of non-combustible, non-absorptive insulating material such as slate or marble, somewhat larger than the rheostat, which shall be secured in position independently of the rheostat supports. Bolts for supporting the rheostat shall be countersunk at least $\frac{1}{4}$ inch below the surface at the back of the slab and filled. For proper mechanical strength, slab should be of a thickness consistent with the size and weight of the rheostat, and in no case to be less than $\frac{1}{2}$ inch.

If resistance devices are installed in rooms where dust or combustible flyings would be liable to accumulate on them, they should be equipped with a dust-proof face plate.

b. Where protective resistances are necessary in connection with automatic rheostats incandescent lamps may be used, provided that they do not

carry or control the main current nor constitute the regulating resistance of the device.

When so used, lamps must be mounted in porcelain receptacles upon non-combustible supports, and must be so arranged that they cannot have impressed upon them a voltage greater than that for which they are rated. They must in all cases be provided with a name-plate, which shall be permanently attached beside the porcelain receptacle or receptacles and stamped with the candle-power and voltage of the lamp or lamps to be used in each receptacle.

c. Wherever insulated wire is used for connection between resistances and the contact plate of a rheostat, the insulation must be slow burning (see No. 43). For large field rheostats and similar resistances, where the contact plates are not mounted upon them, the connecting wires may be run together in groups so arranged that the maximum difference of potential between any two wires in a group shall not exceed 75 volts. Each group of wires must either be mounted on non-combustible, non-absorptive insulators giving at least $\frac{1}{4}$ inch separation from surface wired over, or, where it is necessary to protect the wires from mechanical injury or moisture, be run in *approved* lined conduit or equivalent.

5. Lightning Arresters.—(For construction rules, see No. 63.)

a. Must be attached to each wire of every overhead circuit connected with the station.

It is recommended to all electric light and power companies that arresters be connected at intervals over systems in such numbers and so located as to prevent ordinary discharges entering (over the wires) buildings connected to the lines.

b. Must be located in readily accessible places away from combustible materials, and as near as practicable to the point where the wires enter the building.

In all cases, kinks, coils and sharp bends in the wires between the arresters and the outdoor lines must be avoided as far as possible.

The switchboard does not necessarily afford the only location meeting these requirements. In fact, if the arresters can be located in a safe and accessible place away from the board, this should be done, for, in case the arrester should fail or be seriously damaged there would then be less chance of starting arcs on the board.

c. Must be connected with a thoroughly good and permanent ground connection by metallic strips or wires having a conductivity not less than that of a No. 6 B. & S. gage copper wire, which must be run as nearly in a straight line as possible from the arresters to the ground connection.

Ground wires for lightning arresters must not be attached to gas pipes within the buildings.

It is often desirable to introduce a choke coil in circuit between the arresters and the dynamo. In no case should the ground wires from lightning arresters be put into iron pipes, as these would tend to impede the discharge.

d. All choke coils or other attachments, inherent to the lightning protection equipment, shall have an insulation from the ground or other conductors equal at least to the insulation demanded at other points of the circuit in the station.

6. Care and Attendance.—a. A competent man must be kept on duty where generators are operating. b. Oily waste must be kept in approved metal cans and removed daily.

Approved waste cans shall be made of metal, with legs raising can three inches from the floor, and with self-closing covers.

7. Testing and Insulation Resistance.—a. All circuits except such as are permanently grounded in accordance with No. 13 A must be provided with reliable ground detectors. Detectors which indicate continuously and give an instant and permanent indication of a ground are preferable. Ground wires from detectors must not be attached to gas pipes within the building.

b. Where continuously indicating detectors are not feasible, the circuits should be tested at least once a day, and preferably oftener.

c. Data obtained from all tests must be preserved for examination by the Inspection Department having jurisdiction.

These rules on testing to be applied at such places as may be designated by the Inspection Department having jurisdiction.

8 Motors.—The use of motors operating at a potential in excess of 550 volts will only be approved when every practicable safeguard has been provided. Plans for such installations should be submitted to the Inspection Department having jurisdiction before any work is begun.

a. Must, when operating at a potential in excess of 550 volts, have no exposed live metal parts, and have their base frames permanently and effectively grounded.

Motors operating at a potential of 550 volts or less must be thoroughly insulated from the ground wherever feasible. Wooden base frames used for this purpose, and wooden floors, which are depended upon for insulation where, for any reason, it is necessary to omit the base frames, must be kept filled to prevent absorption of moisture, and must be kept clean and dry. Where frame insulation is impracticable, the Inspection Department having jurisdiction may, in writing, permit its omission, in which case the frame must be permanently and effectively grounded.

A high-potential machine should be surrounded with an insulated platform. This may be made of wood, mounted on insulating supports, and so arranged that a man must stand upon it in order to touch any part of the machine.

In case of a machine having an insulated frame, if there is trouble from static electricity due to belt friction, it should be overcome by placing near the belt a metallic comb connected to the earth, or by grounding the frame through a resistance of not less than 300,000 ohms.

b. Motors operating at a potential of 550 volts or less must be wired with the same precautions as required by rules in Class "C" for wires carrying a current of the same volume.

Motors operating at a potential between 550 and 3,500 volts must be wired with approved multiple conductor, metal sheathed cable in approved unlined metal conduit firmly secured in place. The metal sheath must be permanently and effectively grounded, and the construction and installation of the conduit must conform to rules for interior conduits (see No. 25 and No. 49 a, j, and k), except that at outlets approved outlet bushings shall be used.

The motor leads or branch circuits must be designed to carry a current at least 25 per cent greater than that for which the motor is rated, in order to provide for the inevitable occasional overloading of the motor and the increased current required in starting, without overfusing the wires; but where the wires under this rule would be overfused, in order to provide for the starting current, as in the case of many of the alternating current motors, the wires must be of such size as to be properly protected by these larger fuses.

The insulation of the several conductors for high potential motors, where leaving the metal sheath at outlets, must be thoroughly protected from moisture and mechanical injury. This may be accomplished by means of a pot head or some equivalent method. The conduit must be substantially bonded to the metal casings of all fittings and apparatus connected to the inside high tension circuit. It would be much preferable to make the conduit system continuous throughout by connecting the conduit to fittings and motors by means of screw joints, and this construction is strongly recommended wherever practicable.

High potential motors should preferably be so located that the amount of inside wiring will be reduced to a minimum. Inspection Department having jurisdiction may permit the wire for high potential motors to be installed according to the general rules for high potential systems when the outside wires directly enter a motor room see Section 7. Under these conditions there would generally be but a few feet of wire inside the building and none outside the motor room.

c. Each motor and resistance box must be protected by a cut-out and controlled by a switch (see No. 17 a), said switch plainly indicating whether "on" or "off." With motors of one-fourth horse power or less, on circuits where the voltage does not exceed 300, No. 21 d must be complied with, and single pole switches may be used as allowed in No. 22 c. The switch and rheostat must be located within sight of the motor, except in cases where special permission to locate them elsewhere is given, in writing, by the Inspection Department having jurisdiction.

The use of circuit-breakers with motors is recommended, and may be required by the Inspection Department having jurisdiction.

Where the circuit-breaking device on the motor-starting rheostat disconnects all wires of the circuit, the switch called for in this section may be omitted.

Overload-release devices on motor-starting rheostats will not be considered to take the place of the cut-out required by this section if they are inoperative during the starting of the motor.

The switch is necessary for entirely disconnecting the motor when not in use, and the cut-out to protect the motor from excessive currents due to accidents or careless handling when starting. An automatic circuit-breaker disconnecting all wires of the circuit may, however, serve as both switch and cut-out.

In general, motors should preferably have no exposed live parts.

d. Rheostats must be so installed as to comply with *all* the requirements of No. 4. Auto starters must comply with requirements of No. 4 c.

Starting rheostats and auto starters, unless equipped with tight casings enclosing all current-carrying parts, should be treated about the same as knife switches, and in all wet, dusty or linty places, should be enclosed in dust-tight, fireproof cabinets. If a special motor room is provided, the starting apparatus and safety devices should be included within it. Where there is any liability of short circuits across their exposed live parts being caused by accidental contacts, they should either be enclosed in cabinets, or else a railing should be erected around them to keep unauthorized persons away from their immediate vicinity.

e. Must not be run in series-multiple or multiple-series, except on constant potential systems, and then only by special permission of the Inspection Department having jurisdiction.

f. Must be covered with a waterproof cover when not in use, and, if deemed necessary by the Inspection Department having jurisdiction, must be enclosed in an *approved* case.

When it is necessary to locate a motor in the vicinity of combustibles or in wet or very dusty or dirty places, it is generally advisable to enclose it as above. Such enclosures should be readily accessible, dust proof and sufficiently ventilated to prevent an excessive rise of temperature. The sides should preferably be made largely of glass, so that the motor may be always plainly visible. This lessens the chance of its being neglected, and allows any derangement to be at once noticed.

The use of enclosed type motor is recommended in dusty places, being preferable to wooden boxing. From the nature of the question the decision as to details of construction must be left to the Inspection Department having jurisdiction to determine in each instance.

g. Must, when combined with ceiling fans, be hung from insulated hooks, or else there must be an insulator interposed between the motor and its support.

h. Must each be provided with a name-plate, giving the makers' name, the capacity in volts and amperes, and the normal speed in revolutions per minute.

i. Terminal blocks when used on motors must be made of *approved* non-combustible, non-absorptive, insulating material such as slate, marble or porcelain.

j. Variable speed motors, unless of special and appropriate design, if controlled by means of field regulation, must be so arranged and connected that they cannot be started under weakened field.

9. **Railway Power Plants.**—a. Each feed wire before it leaves the station must be equipped with an *approved* automatic circuit-breaker (see No. 52) or other device, which will immediately cut off the current in case of an accidental ground. This device must be mounted on a fireproof base, and in full view and reach of the attendant.

10. **Storage or Primary Batteries.**—a. When current for light and power is taken from primary or secondary batteries, the same general regulations must be observed as apply to similar apparatus fed from dynamo generators developing the same difference of potential.

b. Storage battery rooms must be thoroughly ventilated.

c. Special attention is directed to the rules for wiring in rooms where acid fumes exist (see No. 24, i and j).

d. All secondary batteries must be mounted on non-absorptive, non-combustible insulators, such as glass or thoroughly vitrified and glazed porcelain.

e. The use of any metal liable to corrosion must be avoided in cell connections of secondary batteries.

11. **Transformers.**—(For construction rules, see No. 62.) (See also Nos. 13, 13A, 36.) a. In central or sub-stations the transformers must be so placed that smoke from the burning out of the coils or the boiling over of the oil (where oil filled cases are used) could do no harm.

If the insulation in a transformer breaks down, considerable heat is likely to be developed. This would cause a dense smoke, which might be mistaken for a fire and result in water being thrown into the building, and a heavy loss thereby entailed. Moreover, with oil-cooled transformers, especially if the cases are filled too full, the oil may become ignited and boil over, producing a very stubborn fire.

b. In central or sub-stations, casings of all transformers must be permanently and effectively grounded.

Transformers used exclusively to supply current to switchboard instruments need not be grounded, provided they are thoroughly insulated.

Class B.—OUTSIDE WORK.

(LIGHT, POWER AND HEAT. FOR SIGNALING SYSTEMS, SEE CLASS E.)

ALL SYSTEMS AND VOLTAGES.

12. Wires.—a. Line wires must have an *approved* weatherproof or rubber insulating covering (see No. 44 and No. 41). That portion of the service wires between the main cut-out and switch and the first support from the cut-out or switch on outside of the building must have an approved rubber insulating covering (see No. 41), but from the above-mentioned support to the line, may have an approved weatherproof insulating covering (see No. 44), if kept free from awnings, swinging signs, shutters, etc.

b. Must be so placed that moisture cannot form a cross connection between them, not less than a foot apart, and not in contact with any substance other than their insulating supports. Wooden blocks to which insulators are attached must be covered over their entire surface with at least two coats of waterproof paint.

c. Must be at least seven feet above the highest point of flat roofs, and at least one foot above the ridge of pitched roofs, over which they pass or to which they are attached.

Roof structures are frequently found which are too low or much too light for the work, or which have been carelessly put up. A structure which is to hold the wires a proper distance above the roof in all kinds of weather must not only be of sufficient height, but must be substantially constructed of strong material.

d. Must be protected by dead insulated guard irons or wires from possibility of contact with other conducting wires or substances to which current may leak. Special precautions of this kind must be taken where sharp angles occur, or where any wires might possibly come in contact with electric light or power wires.

Crosses, when unavoidable, should be made as nearly at right angles as possible.

e. Must be provided with petticoat insulators of glass or porcelain. Porcelain knobs or cleats and rubber hooks will not be approved.

f. Must be so spliced or joined as to be both mechanically and electrically secure without solder. The joints must then be soldered, to insure preservation, and covered with an insulation equal to that on the conductors.

All joints must be soldered, unless made with some form of *approved* splicing device. This ruling applies to joints and splices in all classes of wiring covered by these rules.

g. Must, where they enter buildings, have drip loops outside, and the holes through which the conductors pass must be bushed with non-combustible, non-absorptive, insulating tubes slanting upward toward the inside.

For low potential systems the service wires may be brought into buildings through a single iron conduit. The conduit to be curved downward at its outer end and carefully sealed or equipped with an approved service-head to prevent the entrance of moisture. The outer end must be at least one foot from any wood-work and the inner end must extend to the service cut-out, and if a cabinet is required by the Code must enter the cabinet in a manner similar to that described in fine print note under No. 25b.

h. Electric light and power wires must not be placed on the same cross-arm with telegraph, telephone or similar wires, and when placed on the same pole with such wires the distance between the two inside pins of each cross-arm must not be less than twenty-six inches.

i. The metallic sheaths to cables must be permanently and effectively connected to "earth."

Trolley Wires.—j. Must not be smaller than No. 0 B. & S. gage copper or No. 4 B. & S. gage silicon bronze, and must readily stand the strain upon them when in use.

k. Must have a double insulation from the ground. In wooden pole construction the pole will be considered as one insulation.

l. Must be capable of being disconnected at the power plant, or of being divided into sections, so that, in case of fire on the railway route, the current may be shut off from that particular section and not interfere with the work of the firemen. This rule also applies to feeders.

m. Must be safely protected against accidental contact where crossed by other conductors.

Guard wires should be insulated from the ground and should be electrically disconnected in sections of not more than 300 feet in length.

Ground Return Wires.—n. For the diminution of electrolytic corrosion of underground metal work, ground return wires must be so arranged that the difference of potential between the grounded dynamo terminal and any point on the return circuit will not exceed twenty-five volts.

It is suggested that the positive pole of the dynamo be connected to the trolley line, and that whenever pipes or other underground metal work are found to be electrically positive to the rails or surrounding earth, that they be connected by conductors arranged so as to prevent as far as possible current flow from the pipes into the ground.

12 A. Constant-Potential Pole Lines, Over 5,000 Volts.—(Overhead lines of this class unless properly arranged may increase the fire loss from the following causes:—Accidental crosses between such lines and low-potential lines may allow the high-voltage current to enter buildings over a large section of adjoining country. Moreover, such high-voltage lines, if carried close to buildings, hamper the work of firemen in case of fire in the building. The object of these rules is so to direct this class of construction that no increase in fire hazard will result, while at the same time care has been taken to avoid restrictions which would unreasonably impede progress in electrical development.

It is fully understood that it is impossible to frame rules which will cover all conceivable cases that may arise in construction work of such an extended and varied nature, and it is advised that the Inspection Department having jurisdiction be freely consulted as to any modification of the rules in particular cases.)

a. Every reasonable precaution must be taken in arranging routes so as to avoid exposure to contacts with other electric circuits. On existing lines, where there is a liability to contact, the route should be changed by mutual agreement between the parties in interest wherever possible.

b. Such lines should not approach other pole lines nearer than a distance equal to the height of the taller pole line, and such lines should not be on the same poles with other wires, except that signaling wires used by the Company operating the high-pressure system, and which do not enter property other than that owned or occupied by such Company, may be carried over the same poles.

c. Where such lines must necessarily be carried nearer to other pole lines than is specified in Section b above, or where they must necessarily be carried on the same poles with other wires, extra precautions to reduce the liability of a breakdown to a minimum must be taken, such as the use of wires of ample mechanical strength, widely spaced cross-arms, short spans, double or extra heavy cross-arms, extra heavy pins, insulators, and poles thoroughly supported. If carried on the same poles with other wires, the high-pressure wires must be carried at least three feet above the other wires.

d. Where such lines cross other lines, the poles of both lines must be of heavy and substantial construction.

Whenever it is feasible, end-insulator guards should be placed on the cross-arms of the upper line. If the high-pressure wires cross below the other lines, the wires of the upper line should be dead-ended at each end of the span to double-grooved, or to standard transposition insulators, and the line completed by loops.

One of the following forms of construction must then be adopted:—

1. The height and length of the cross-over span may be made such that the shortest distance between the lower cross-arms of the upper line and any wire of the lower line will be greater than the length of the cross-over span, so that a wire breaking near one of the upper pins would not be long enough to reach any wire of the lower line. The high-pressure wires should preferably be above the other wires.

2. A joint pole may be erected at the crossing point, the high-pressure wires being supported on this pole at least three feet above the other wires. Mechanical guards or supports must then be provided, so that in case of the breaking of any upper wire, it will be impossible for it to come into contact with any of the lower wires.

Such liability of contact may be prevented by the use of suspension wires, similar to those employed for suspending aerial telephone cables, which will prevent the high-pressure wires from falling, in case they break. The suspension wires should be supported on high-potential insulators, should have ample mechanical strength, and should be carried over the high-pressure wires for one span on each side of the joint pole, or where suspension wires are not desired guard wires may be carried above and below the lower wires for one span on each side of the joint pole, and so spread that a falling high-pressure wire would be held out of contact with the lower wires.

Such guard wires should be supported on high-potential insulators or should be grounded. When grounded, they must be of such size, and so connected and earthed, that they can surely carry to ground any current which may be delivered by any of the high-pressure wires. Further, the construction must be such that the guard wires will not be destroyed by any arcing at the point of contact likely to occur under the conditions existing.

3. Whenever neither of the above methods is feasible, a screen of wire should be interposed between the lines at the cross-over. This screen should be supported on high tension insulators or grounded, and should be of such construction and strength as to prevent the upper wires from coming into contact with the lower ones.

If the screen is grounded, each wire of the screen must be of such size and so connected and earthed that it can surely carry to ground any current which may be delivered by any of the high-pressure wires. Further, the construction must be such that the wires of screen will not be destroyed by any arcing at the point of contact likely to occur under the conditions existing.

e. When it is necessary to carry such lines near buildings, they must be at such height and distance from the building as not to interfere with firemen in event of fire; therefore, if within 25 feet of a building, they must be carried at a height not less than that of the front cornice, and the height must be greater than that of the cornice, as the wires come nearer to the building in accordance with the following table:—

Distance of wire from building.	Elevation of wire above cornice of building.	Distance of wire from building.	Elevation of wire above cornice of building.
Feet.	Feet.	Feet.	Feet.
25	0	10	6
20	2	5	8
15	4	2½	9

It is evident that where the roof of the building continues nearly in line with the walls, as in Mansard roofs, the height and distance of the line must be reckoned from some part of the roof instead of from the cornice.

13. Transformers.—(For construction rules, see No. 62.) (See also Nos. 11, 13 A and 36.) [Where transformers are to be connected to high-voltage circuits, it is necessary in many cases, for best protection to life and property, that the secondary system be permanently grounded, and provision should be made for it when the transformers are built.]

a. Must not be placed inside of any building, excepting central stations and sub-stations, unless by special permission of the Inspection Department having jurisdiction.

An outside location is always preferable; first, because it keeps the high-voltage primary wires entirely out of the building, and second, for the reasons given in the note to No. 11a.

b. Must not be attached to the outside walls of buildings, unless separated therefrom by substantial supports.

It is recommended that transformers be not attached to frame buildings when any other location is practicable.

13A. Grounding Low-Potential Circuits.—The grounding of low-potential circuits under the following regulations is only allowed when such circuits are so arranged that under normal conditions of service there will be no passage of current over the ground wire.

Direct-Current 3-Wire Systems.—a. Neutral wire may be grounded and when grounded the following rules must be complied with:—

1. Must be grounded at the Central Station on a metal plate buried in coke beneath permanent moisture level, and also through all available underground water and gas pipe systems.
2. In underground systems the neutral wire must also be grounded at each distributing box through the box.
3. In overhead systems the neutral wire must be grounded every 500 feet, as provided in Sections c to g.

Inspection Departments having jurisdiction may require grounding if they deem it necessary.

Two-wire direct-current systems having no accessible neutral point are not to be grounded.

Alternating-Current Secondary Systems.—b. Transformer secondaries of distributing systems should preferably be grounded, and when grounded, the following rules must be complied with:—

1. The grounding must be made at the neutral point or wire, whenever a neutral point or wire is accessible.
2. When no neutral point or wire is accessible one side of the secondary circuit may be grounded, provided the maximum difference of potential between the grounded point and any other point in the circuit does not exceed 250 volts.
3. The ground connections must be at the transformer or on the individual service as provided in sections c to g, and when transformers feed systems with a neutral wire, the neutral wire must also be grounded at least every 250 feet for overhead systems, and every 500 feet for underground systems.

Inspection Departments having jurisdiction may require grounding if they deem it necessary.

Ground Connections.—c. When the ground connection is inside of any building, or the ground wire is inside of, or attached to any building (except Central or Sub-stations) the ground wire must be of copper and have an approved rubber insulating covering National Electric Code Standard, for from 0 to 600 volts. (See No. 41.)

d. The ground wire in direct-current 3-wire systems must not at Central Stations be smaller than the neutral wire and not smaller than No. 4 B. & S. gage elsewhere. The ground wire in alternating-current systems must never be less than No. 4 B. & S. gage.

On three-phase system, the ground wire must have a carrying capacity equal to that of any one of the three mains.

e. The ground wire should, except for Central Stations and transformer sub-stations, be kept outside of buildings as far as practicable, but may be directly attached to the building or pole by cleats or straps or on porcelain knobs. Staples must never be used. The wire must be carried in as nearly a straight line as practicable, avoiding kinks, coils and sharp bends, and must be protected when exposed to mechanical injury.

This protection can be secured by use of an approved moulding, and as a rule the ground wire on the outside of a building should be in moulding at all places where it is in within seven feet from the ground.

f. The ground connection for Central Stations, transformer sub-stations, and banks of transformers must be made through metal plates buried in coke below permanent moisture level, and connection should also be made to all available underground piping systems including the lead sheath of underground cables.

g. For individual transformers and building services, the ground connection may be made as in Section f, or may be made to water piping systems running into buildings. This connection may be made by carrying the ground wire into the cellar and connecting on the street side of meters, main cocks, etc.

Where it is necessary to run the ground wire through any part of a building it shall be protected by approved porcelain bushings through walls or partitions and shall be run in approved moulding, except that in basements it may be supported on porcelain.

In connecting a ground wire to a piping system, the wire should be sweat into a lug attached to an approved clamp, and the clamp firmly bolted to the water pipe after all rust and scale have been removed; or be soldered into a brass plug and the plug forcibly screwed into a pipe-fitting, or, where the pipes are cast iron, into a hole tapped into the pipe itself. For large stations, where connecting to underground pipes with bell and spigot joints, it is well to connect to several lengths, as the pipe joints may be of rather high resistance.

Where ground plates are used, a No. 16 Stubbs' gage copper plate, about 3 x 6 feet in size, with about 2 feet of crushed coke or charcoal, about pea size, both under and over it, would make a ground of sufficient capacity for a moderate-sized station, and would probably answer for the ordinary sub-station or bank of transformers. For a large central station, a plate with considerable more area might be necessary, depending upon the other underground connections available. The ground wire should be riveted to the plate in a number of places, and soldered for its whole length. Perhaps even better than a copper plate is a cast-iron plate with projecting forks, the idea of the fork being to distribute the connection to the ground over a fairly broad area, and to give a large surface contact. The ground wire can probably best be connected to such a cast-iron plate by soldering it into brass plugs screwed into holes tapped in the plate. In all cases, the joint between the plate and the ground wire should be thoroughly protected against corrosion by painting it with waterproof paint or some equivalent.

CLASS C.—INSIDE WORK.

(LIGHT POWER AND HEAT. FOR SIGNALING SYSTEMS, SEE CLASS E.)

ALL SYSTEMS AND VOLTAGES

GENERAL RULES.

14. Wires.—(For special rules, see Nos. 16, 18, 24, 35, 38 and 39.)

a. Must not be of smaller size than No. 14 B. & S. gage, except as allowed under Nos. 24v and 45b.

b. Tie wires must have an insulation equal to that of the conductors they confine.

The use of some form of confining knob or insulator which will dispense with tie wires is recommended.

c. Must be so spliced or joined as to be both mechanically and electrically secure without solder. The joints must then be soldered to insure preservation, and covered with an insulation equal to that on the conductors.

Stranded wires must be soldered before being fastened under clamps or binding screws, and whether stranded or solid, when they have a conductivity greater than that of No. 8 B. & S. gage they must be soldered into lugs for all terminal connections.

All joints must be soldered unless made with some form of approved splicing device. This ruling applies to joints and splices in all classes of wiring covered by these rules.

d. Must be separated from contact with walls, floors, timbers or partitions through which they may pass by non-combustible, non-absorptive insulating tubes, such as glass or porcelain, except as provided in No. 24u.

Bushings must be long enough to bush the entire length of the hole in one continuous piece, or else the hole must first be bushed by a continuous waterproof tube. This tube may be a conductor, such as iron pipe, but in that case an insulating pushing must be pushed into each end of it, extending far enough to keep the wire absolutely out of contact with the pipe.

e. Must be kept free from contact with gas, water or other metallic piping, or any other conductors or conducting material which they may cross, by some continuous and firmly fixed non-conductor, creating a permanent separation. Deviations from this rule may sometimes be allowed by special permission.

Where one wire crosses another wire the best and usual means of separating them is by a porcelain tube on one of the wires. The tubing must be prevented from moving out of place either by a cleat or knob on each end, or by taping it securely in place.

The same method may be adopted where wires pass close to iron pipes, beams, etc., or where the wires are above the pipes, as is generally the case, ample protection can frequently be secured by supporting the wires with a porcelain cleat placed as nearly above the pipe as possible.

This rule must not be construed as in any way modifying No. 24, Sections h and j.

f. Must be so placed in wet places that an air space will be left between conductors and pipes in crossing, and the former must be run in such a way that they cannot come in contact with the pipe accidentally. Wires should be run over, rather than under, pipes upon which moisture is likely to gather or which, by leaking, might cause trouble on a circuit.

g. The installation of electrical conductors in wooden moulding, or on insulators, in elevator shafts will not be approved, but conductors may be installed in such shafts if encased in approved metal conduits.

15. Underground Conductors.—a. Must be protected against moisture and mechanical injury where brought into a building, and all combustible material must be kept from the immediate vicinity.

b. Must not be so arranged as to shunt the current through a building around any catch-box.

c. Where underground service enters building through tubes, the tubes shall be tightly closed at outlets with asphaltum or other non-conductor, to prevent gases from entering the building through such channels.

d. No underground service from a subway to a building shall supply more than one building except by written permission from the Inspection Department having jurisdiction.

16. Table of Carrying Capacity of Wires.—a. The following table, showing the allowable carrying capacity of copper wires and cables of ninety-eight per cent conductivity, according to the standard adopted by the American Institute of Electrical Engineers, must be followed in placing interior conductors (See page 1388.)

For insulated aluminum wire the safe carrying capacity is eighty-four per cent of that given in the following tables for copper wire with the same kind of insulation.

TABLE A. Rubber Insulation. See No. 41.		TABLE B. Other Insulations. See No. 42 to 44.		TABLE A. Concl'd. Amperes.		TABLE B Concl'd. Amperes.	
B. & S. Gage.	Amperes.	Amperes.	Circular Mils.	Circular Mils.	Amperes.	Amperes.	Amperes.
18	3	5	1,624	200,000	200	300	300
16	6	8	2,583	300,000	270	400	400
14	12	16	4,107	400,000	320	500	500
12	17	23	6,530	500,000	390	590	590
10	24	32	10,380	600,000	450	680	680
8	33	46	16,510	700,000	500	760	760
6	46	65	26,250	800,000	550	840	840
5	54	77	33,100	900,000	600	920	920
4	65	92	41,740	1,000,000	650	1,000	1,000
3	76	110	52,630	1,100,000	690	1,080	1,080
2	90	131	66,370	1,200,000	730	1,150	1,150
1	107	156	83,690	1,300,000	770	1,220	1,220
0	127	185	105,500	1,400,000	810	1,290	1,290
00	150	220	133,100	1,500,000	850	1,360	1,360
000	177	262	167,800	1,600,000	890	1,430	1,430
0000	210	312	211,600	1,700,000	930	1,490	1,490
				1,800,000	970	1,550	1,550
				1,900,000	1,010	1,610	1,610
				2,000,000	1,050	1,670	1,670

The lower limit is specified for rubber-covered wires to prevent gradual deterioration of the high insulations by the heat of the wires, but not from fear of igniting the insulation. The question of drop is not taken into consideration in the above tables.

The carrying capacity of Nos. 16 and 18 B. & S. gage wire is given, but no smaller than No. 14 is to be used, except as allowed under Nos. 24v and 45b.

17. Switches, Cut-Outs, Circuit-Breakers, Etc.—(For construction rules, see Nos. 51, 52 and 53.) a. On constant potential circuits, all service switches and all switches controlling circuits supplying current to motors or heating devices, and all cut-outs, unless otherwise provided (for exceptions as to switches see Nos. 8c and 21a; for exceptions as to cut-outs see No. 21a and b) must be so arranged that the cut-outs will protect and the opening of the switch or circuit-breaker will disconnect all of the wires; that is, in the two-wire system the two wires, and the three-wire system the three wires, must be protected by the cut-out and disconnected by the operation of the switch or circuit-breaker.

This, of course, does not apply to the grounded circuit of street railway systems.

b. Must not be placed in the immediate vicinity of easily ignitable stuff or where exposed to inflammable gases or dust or to flyings of combustible material.

When the occupancy of a building is such that switches, cut-outs, etc., cannot be located so as not to be exposed to dust or flyings of combustible material they must be enclosed in approved dust-proof cabinets with self-closing doors, except oil switches and circuit-breakers which have dust-tight casings.

c. Must, when exposed to dampness, either be enclosed in a moisture-proof box or mounted on porcelain knobs.

The cover of the box should be so made that no moisture which may collect on the top or sides of the box can enter it.

d. Time switches, sign flashers and similar appliances must be of approved design and enclosed in a steel box or cabinet lined with fire-resisting material.

The cover of the box should be so made that no moisture which may collect on the top or sides of the box can enter it.

If a steel box is used, the minimum thickness of the steel must be 0.128 of an inch (No. 8 B. & S. gage).

If a cabinet is used, it must be lined with marble or slate at least three-eighths of an inch thick, or with steel not less than 0.128 of an inch thick. Box or cabinet must be so constructed that when switch operates blade shall clear the door by at least one inch.

CONSTANT-CURRENT SYSTEMS.

PRINCIPALLY SERIES ARC LIGHTING.

18. Wires.—(See also Nos. 14, 15 and 16.) a. Must have an *approved* rubber insulating covering (see No. 41).

b. Must be arranged to enter and leave the building through an *approved* double-contact service switch (see No. 51b), mounted in a non-combustible case, kept free from moisture, and easy of access to police or firemen.

c. Must always be in plain sight, and never encased, except when *required* by the Inspection Department having jurisdiction.

d. Must be supported on glass or porcelain insulators, which separate the wire at least one inch from the surface wired over and must be kept *rigidly* at least 8 inches from each other, except within the structure of lamps, on hanger-boards or in cut-out boxes, or like places, where a less distance is necessary.

e. Must, on side walls be protected from mechanical injury by a substantial boxing, retaining an air space of one inch around the conductors, closed at the top (the wires passing through bushed holes), and extending not less than 7 feet from the floor. When crossing floor timbers in cellars, or in rooms where they might be exposed to injury, wires must be attached by their insulating supports to the under side of a wooden strip not less than one-half an inch in thickness. Instead of the running-boards, guard strips on each side of and close to the wires will be accepted. These strips to be not less than seven-eighths of an inch in thickness and at least as high as the insulators.

Except on joisted ceilings, a strip one-half of an inch thick is not considered sufficiently stiff and strong. For spans of say eight or ten feet, where there is but little vibration, one-inch stock is generally sufficiently stiff; but where the span is longer than this or there is considerable vibration, still heavier stock should be used.

19. Series Arc Lamps.—(For construction rules, see No. 57.)

a. Must be carefully isolated from inflammable material.

b. Must be provided at all times with a glass globe surrounding the arc, and securely fastened upon a closed base. Broken or cracked globes must not be used.

c. Must be provided with a wire netting (having a mesh not exceeding one and one-fourth inches) around the globe, and an *approved* spark arrester (see No. 58), when readily inflammable material is in the vicinity of the lamps, to prevent escape of sparks of carbon or melted copper. It is recommended that plain carbons, not copper-plated, be used for lamps in such places.

Outside arc lamps must be suspended at least eight feet above sidewalks. Inside arc lamps must be placed out of reach or suitably protected.

Arc lamps, when used in places where they are exposed to flyings of easily inflammable material, should have the carbons enclosed completely in a tight globe in such manner as to avoid the necessity for spark arresters.

"Enclosed arc" lamps, having tight inner globes, may be used, and the requirements of Sections b and c above would, of course, not apply to them, except that a

wire netting around the inner globe may in some cases be required if the outer globe is omitted.

d. Where hanger-boards (see No. 56) are not used, lamps must be hung from insulating supports other than their conductors.

e. Lamps when arranged to be raised and lowered, either for carboning or other purposes, shall be connected up with stranded conductors from the last point of support to the lamp, when such conductor is larger than No. 14 B. & S. gage.

20. Incandescent Lamps in Series Circuits.—a. Must have the conductors installed as required in No. 18, and each lamp must be provided with an automatic cut-out.

b. Must have each lamp suspended from a hanger-board by means of rigid tube.

c. No electro-magnetic device for switches and no multiple-series or series-multiple system of lighting will be approved.

d. Must not under any circumstances be attached to gas fixtures.

CONSTANT-POTENTIAL SYSTEMS.

GENERAL RULES—ALL VOLTAGES.

21. Automatic Cut-Outs (Fuses and Circuit-Breakers).—(See No. 17, and for construction, Nos. 52 and 53.) [Excepting on main switchboards, or where otherwise subject to expert supervision, circuit-breakers will not be accepted unless fuses are also provided.]

a. Must be placed on all service wires, either overhead or underground, as near as possible to the point where they enter the building and inside the walls, and arranged to cut off the entire current of the building.

Where the switch required by No. 22a is inside the building, the cut-out required by this section must be placed so as to protect it.

For three-wire (not three-phase) systems the fuse in the neutral wire may be omitted, *provided the neutral wire is of equal carrying capacity to the larger of the outside wires, and is grounded as provided for in No. 13A.*

In risks having private plants, the yard wires running from building to building are not generally considered as service wires, so that cut-outs would not be required where the wires enter buildings, provided that the next fuse back is small enough to properly protect the wires inside the building in question.

b. Must be placed at every point where a change is made in the size of wire [unless the cut-out in the larger wire will protect the smaller (see No. 16)].

For three-wire (not three-phase) systems the fuse in the neutral wire, except that called for under No. 21d, may be omitted, *provided the neutral wire is of equal carrying capacity to the larger of the outside wires, and is grounded as provided for in No. 13A.*

c. Must be in plain sight, or enclosed in an *approved* cabinet (see No. 54), and readily accessible. They must not be placed in the canopies or shells of fixtures.

The ordinary porcelain link fuse cut-out will not be approved. Link fuses may be used only when mounted on slate or marble bases conforming to No. 53 and must be enclosed in dust-tight, fireproofed cabinets, except on switchboards located well away from any combustible material, as in the ordinary engine and dynamo room and where these conditions will be maintained.

d. Must be so placed that no set of incandescent lamps requiring more than 660 watts, whether grouped on one fixture or on several fixtures or pendants, will be dependent upon one cut-out.

Special permission may be given in writing by the Inspection Department having jurisdiction, for departure from this rule, in the case of large chandeliers. (For exceptions, see No. 31 A, b, 3[b] and 4[b] for border lights, see List of Fittings for rules for electric signs.) All branches or taps from any three-wire system which are directly connected to lamp sockets or other translating devices, must be run as two-wire circuits if the fuses are omitted in the neutral, or if the difference of potential between the two outside wires is over 250 volts, and both wires of such branch or tap circuits must be protected by proper fuses.

The above rule shall also apply to motors when more than one is dependent on a single cut-out.

The fuses in the branch cut-outs should not have a rated capacity greater than 6 amperes on 110 volt systems, and 3 amperes on 220 volt systems.

The idea is to have a small fuse to protect the lamp socket and the small wire used for fixtures, pendants, etc. It also lessens the chances of extinguishing a large number of lights if a short circuit occurs.

On open work in large mills *approved* link fused rosettes may be used at a voltage of not over 125 and *approved* enclosed fused rosettes at a voltage of not over 250, the fuse in the rosettes not to exceed 3 amperes, and a fuse of over 25 amperes must not be used in the branch circuit.

e. The rated capacity of fuses must not exceed the allowable carrying capacity of the wire as given in No. 16. Circuit-breakers must not be set more than 30 per cent above the allowable carrying capacity of the wire, unless a fusible cut-out is also installed in the circuit.

In the arms of fixtures carrying a single socket a No. 18 B. & S. gage wire supplying one socket will be considered as properly protected by a 6 ampere fuse.

22. Switches.—(See No. 17, and for construction, No. 51.)

a. Must be placed on all service wires, either overhead or underground, in a readily accessible place, as near as possible to the point where the wires enter the building, and arranged to cut off the entire current.

Service cut-out and switch must be arranged to cut off current from all devices including meters.

In risks having private plants the yard wires running from building to building are not generally considered as service wires, so that switches would not be required in each building if there are other switches conveniently located on the mains or if the generators are near at hand.

b. Must always be placed in dry, accessible places, and be grouped as far as possible. (See No. 17 c.) Single-throw knife switches must be so placed that gravity will tend to open rather than close them. Double-throw knife switches may be mounted so that the throw will be either vertical or horizontal as preferred.

When possible, switches should be so wired that blades will be "dead" when switch is open.

If switches are used in rooms where combustible flyings would be likely to accumulate around them, they should be enclosed in dust-tight cabinets. (See note under No. 17 b.) Even in rooms where there are no combustible materials it is better to put all knife switches in cabinets, in order to lessen the danger of accidental short circuits being made across their exposed metal parts by careless workmen.

Up to 250 volts and 30 amperes, *approved indicating snap* switches are advised in preference to knife switches on lighting circuits about the workrooms.

c. Single pole switches must never be used as service switches nor placed in the neutral wire of a three-wire system, except in the two-wire branch or tap circuit described in 21 d.

This, of course, does not apply to the grounded circuits of street railway systems. Three-way switches are considered as single-pole switches and must be wired so that only one pole of the circuit is carried to either switch.

d. Where flush switches or receptacles are used, whether with conduit systems or not, they must be enclosed in boxes constructed of iron or steel. No push button for bells, gas-lighting circuits, or the like shall be placed in the same wall plate with switches controlling electric light or power wiring.

This requires an *approved* box in addition to the porcelain enclosure of the switch or receptacle.

e. Where possible, at all switch or fixture outlets, a $\frac{1}{2}$ -inch block must be fastened between studs or floor timbers flush with the back of lathing to hold tubes, and to support switches or fixtures. When this cannot be done, wooden base blocks not less than $\frac{1}{2}$ -inch in thickness, securely screwed to lathing, must be provided for switches, and also for fixtures which are not attached to gas pipes or conduit.

The above will not be necessary where outlet boxes are used which will give proper support for fixtures, etc.

f. Sub-bases of non-combustible, non-absorptive insulating material, which will separate the wires at least $\frac{1}{2}$ -inch from the surface wired over, must be installed under all snap switches used in exposed knob and cleat work. Sub-bases must also be used in moulding work, but they may be made of hardwood.

23. Electric Heaters.—It is often desirable to connect in multiple with the heaters and between the heater and the switch controlling same, an incandescent lamp of low candle power, as it shows at a glance whether or not the switch is open, and tends to prevent its being left closed through oversight. Inspection Departments having jurisdiction may require this provision to be carried out if they deem it necessary.

a. Must be protected by a cut-out and controlled by indicating switches. Switches must be double pole except when the device controlled does not require more than 660 watts of energy.

- b. Must never be concealed, but must at all times be in plain sight.

Special permission may be given in writing by the Inspection Department having jurisdiction for departure from this rule in certain cases.

- c. Flexible conductors for smoothing irons and sad irons, and for all devices requiring over 250 watts must comply with No. 45 g.

d. For portable heating devices the flexible conductors must be connected to an *approved* plug device, so arranged that the plug will pull out and open the circuit in case any abnormal strain is put on the flexible conductor. This device may be stationary, or it may be placed in the cord itself. The cable or cord must be attached to the heating apparatus in such manner that it will be protected from kinking, chafing or like injury at or near the point of connection.

e. Smoothing irons, sad irons, and other heating appliances that are intended to be applied to inflammable articles, such as clothing, must conform to the above rules so far as they apply. They must also be provided with an approved stand, on which they should be placed when not in use.

An approved automatic attachment which will cut off the current when the iron is not on the stand or in actual use is desirable. Inspection Departments having jurisdiction may require this provision to be carried out if they deem it advisable.

f. Stationary electric heating apparatus, such as radiators, ranges, plate warmers, etc., must be placed in a safe location, isolated from inflammable materials, and be treated as sources of heat.

Devices of this description will often require a suitable heat-resisting material placed between the device and its surroundings. Such protection may best be secured by installing two or more plates of tin or sheet steel with a one-inch air space between, or by alternate layers of sheet steel and asbestos with a similar air space.

g. Must each be provided with name-plate, giving the maker's name and the normal capacity in volts and amperes.

CONSTANT-LOW-POTENTIAL SYSTEMS.

550 VOLTS OR LESS.

Any circuit attached to any machine, or combination of machines, which develops a difference of potential between any two wires, of over ten volts and less than 550 volts, shall be considered as a low-potential circuit, and as coming under this class, unless an approved transforming device is used, which cuts the difference of potential down to ten volts or less. The primary circuit not to exceed a potential of 3,500 volts unless the primary wires are installed in accordance with the requirements as given in No. 12 A, or are underground.

For 550 volt motor equipments a margin of ten per cent above the 550 volt limit will be allowed at the generator or transformer.

Before pressure is raised above 300 volts on any previously existing system of wiring, the whole must be strictly brought up to all of the requirements of the rules at date.

24. Wires.—GENERAL RULES. (See also Nos. 14, 15 and 16.)

a. *Must be so arranged that under no circumstances will there be a difference of potential of over 300 volts between any bare metal parts in any distributing switch or cut-out cabinet, or equivalent center of distribution.*

This rule is not intended to prohibit the placing of switches or single pole cut-outs for motor systems of voltages above 300 in cabinets, but would require that the cabinets be divided by *approved* barriers so arranged that no one section shall contain more than one switch nor more than one single pole cut-out.

b. Must not be laid in plaster, cement or similar finish, and must never be fastened with staples.

c. Must not be fished for any great distance, and only in places where the inspector can satisfy himself that the rules have been complied with.

d. Twin wires must never be used, except in conduits, or where flexible conductors are necessary.

e. Must be protected on side walls from mechanical injury. When crossing floor timbers in cellars, or in rooms where they might be exposed to injury, wires must be attached by their insulating supports to the under side of a wooden strip, not less than one-half inch in thickness and not less than three inches in width. Instead of the running-boards, guard strips on each

side of and close to the wires will be accepted. These strips to be not less than seven-eighths of an inch in thickness, and at least as high as the insulators.

Suitable protection on side walls should extend not less than five feet from the floor. This may be secured by substantial boxing, retaining an air space of one inch around the conductors, closed at the top (the wires passing through bushed holes) or by approved metal conduit, or pipe of equivalent strength.

When metal conduit or pipe is used, the insulation of each wire must be reinforced by approved flexible tubing extending from the insulator next below the pipe to the one next above it, unless the conduit is installed according to No. 25 (sections c and f excepted), and the wire used complies with No. 47. The two or more wires of a circuit each with its flexible tubing (when required), if carrying alternating current must, or if direct current, may be placed within the same pipe.

In damp places the wooden boxing may be preferable because of the precautions which would be necessary to secure proper insulation if the pipe were used. With this exception, however, iron piping is considered preferable to the wooden boxing, and its use is strongly urged. It is especially suitable for the protection of wires near belts, pulleys, etc.

f. When run in unfinished attics, will be considered as concealed, and when run in close proximity to water tanks or pipes, will be considered as exposed to moisture.

In unfinished attics wires are considered as exposed to mechanical injury, and must not be run on knobs on upper edge of joists.

SPECIAL RULES.

For Open Work—In dry places.

g. Must have an approved rubber, slow-burning weatherproof, or slow-burning insulation (see Nos. 41, 42 and 43).

A slow-burning covering, that is, one that will not carry fire, is considered good enough where the wires are entirely on insulating supports. Its main object is to prevent the copper conductors from coming accidentally into contact with each other or anything else.

h. Must be rigidly supported on non-combustible, non-absorptive insulators, which will separate the wires from each other and from the surface wired over in accordance with the following table:—

Voltage.	Distance from Surface.	Distance between Wires.
0 to 300	$\frac{1}{2}$ inch	$2\frac{1}{2}$ inch
301 to 550	1 "	4 "

Rigid supporting requires under ordinary conditions, where wiring along flat surfaces, supports at least every four and one-half feet. If the wires are liable to be disturbed, the distance between supports should be shortened. In buildings of mill construction, mains of not less than No. 8 B. & S. gage, where not liable to be disturbed, may be separated about six inches, and run from timber to timber, not breaking around, and may be supported at each timber only.

This rule not to be interpreted to forbid the placing of the neutral of an Edison three-wire system in the center of a three-wire cleat where the difference of potential between the outside wires is not over 300 volts, provided the outside wires are separated two and one-half inches.

For Open Work—In damp places, or buildings specially subject to moisture or to acid or other fumes liable to injure the wires or their insulation.

i. Must have an approved insulating covering.

For protection against water, rubber insulation must be used. For protection against corrosive vapors, either weatherproof or rubber insulation must be used. (See Nos. 41 and 44.)

j. Must be rigidly supported on non-combustible, non-absorptive insulators, which separate the wire at least one inch from the surface wired over, and must be kept apart at least two and one-half inches for voltages up to 300, and four inches for higher voltages.

Rigid supporting requires under ordinary conditions, where wiring over flat surfaces, supports at least every four and one-half feet. If the wires are liable to be disturbed, the distance between supports should be shortened. In buildings of mill construction, mains of not less than No. 8 B. & S. gage, where not liable to be disturbed, may be separated about six inches, and run from timber to timber, not breaking around, and may be supported at each timber only.

For Moulding Work (Wooden and Metal). (For construction rules see No. 50. See also No. 25 A.)

k. Must have an approved rubber insulating covering. (For wooden moulding see No. 41, for metal moulding see No. 47.)

l. Must never be placed in either metal or wooden moulding in concealed or damp places, or where the difference of potential between any two wires in the same moulding is over 300 volts. *Metal* mouldings must not be used for circuits requiring more than 660 watts of energy.

As a rule, wooden moulding should not be placed directly against a brick wall, as the wall is likely to "sweat" and thus introduce moisture back of the moulding.

m. Must, for alternating current systems if in metal moulding, have the two or more wires of a circuit installed in the same moulding.

It is advised that this be done for direct current systems also, so that they may be changed to alternating systems at any time, induction troubles preventing such a change if the wires are in separate mouldings.

For Conduit Work.

n. Must have an *approved* rubber insulating covering (see No. 47).

o. Must not be drawn in until all mechanical work on the building has been, as far as possible, completed.

Conductors in vertical conduit risers must be supported within the conduit system in accordance with the following table:—

No. 14 to 0 every 100 feet.

No. 00 to 0000 every 80 feet.

0000 to 350,000 C. M. every 60 feet.

350,000 C. M. to 500,000 C. M. every 50 feet.

500,000 C. M. to 750,000 C. M. every 40 feet.

750,000 C. M. every 35 feet.

A turn of 90 degrees in the conduit system will constitute a satisfactory support, as per above table.

The following methods of supporting cables are recommended:—

1. Junction boxes may be inserted in the conduit system at the required intervals, in which insulating supports of *approved* type must be installed and secured in a satisfactory manner so as to withstand the weight of the conductors attached thereto, the boxes to be provided with proper covers.

2. Cables may be supported in *approved* junction boxes on two or more insulating supports so placed that the conductors will be deflected at an angle of not less than 90 degrees, and carried a distance of not less than twice the diameter of the cable from its vertical position. Cables so suspended may be additionally secured to these insulators by tie wires.

Other methods, if used, must be approved by the Inspection Departments having jurisdiction.

p. Must, for alternating systems, have the two or more wires of a circuit drawn in the same conduit.

It is advised that this be done for direct current systems also, so that they may be changed to alternating systems at any time, induction troubles preventing such a change if the wires are in separate conduits.

The same conduit must never contain circuits of different systems, but may contain two or more circuits of the same system.

For Concealed "Knob and Tube" Work.

q. Must have an *approved* rubber insulating covering (see No. 41).

r. Must be rigidly supported on non-combustible, non-absorptive insulators which separate the wire at least one inch from the surface wired over. Should preferably be run singly on separate timbers, or studdings, and must be kept at least five inches apart.

Must be separated from contact with the walls, floor timbers and partitions through which they may pass by non-combustible, non-absorptive insulating tubes, such as glass or porcelain.

Rigid supporting requires under ordinary conditions, where wiring along flat surface, supports at least every four and one-half feet. If the wires are liable to be disturbed the distance between supports should be shortened.

At distributing centers, outlets or switches where space is limited and the five-inch separation cannot be maintained, each wire must be separately encased in a continuous length of approved flexible tubing.

Wires passing through timbers at the bottom of plastered partitions must be protected by an additional tube extending at least four inches above the timber.

s. When in a concealed knob and tube system, it is impracticable to place the whole of a circuit on non-combustible supports of glass or porcelain, that portion of the circuit which cannot be so supported must be installed with *approved* metal conduit, or *approved* armored cable (see No. 24 t), ex-

cept that if the difference of potential between the wires is not over 300 volts, and if the wires are not exposed to moisture, they may be fished if separately encased in *approved* flexible tubing, extending in continuous lengths from porcelain support to porcelain support, from porcelain support to outlet, or from outlet to outlet.

t. Mixed concealed knob and tube work as provided for in No. 24 s, must comply with requirements of No. 24 n to p, and No. 25, when conduit is used, and with requirements of No. 24 A, when armored cable is used.

u. Must at all outlets, except where conduit is used, be protected by *approved* flexible insulating tubing, extending in continuous lengths from the last porcelain support to at least one inch beyond the outlet. In the case of combination fixtures the tubes must extend at least flush with outer end of gas cap.

It is recommended but not required that *approved* outlet boxes or plates be installed at all outlets in concealed "knob and tube" work, the wires to be protected by *approved* flexible insulating tubing, extending in continuous lengths from the last porcelain support into the box.

For Fixture Work. v. Must have an *approved* rubber insulating covering (see No. 46), and be not less in size than No. 18 B. & S. gage.

See No. 46 a, fine print note, for exceptions to the use of rubber-covered wire.

w. Supply conductors, and especially the splices to fixture wires, must be kept clear of the grounded part of gas pipes, and, where shells or outlets boxes are used, they must be made sufficiently large to allow the fulfillment of this requirement.

x. Must, when fixtures are wired outside, be so secured as not to be cut or abraded by the pressure of the fastenings or motion of the fixture.

y. Under no circumstances must there be a difference of potential of more than 300 volts between wires contained in or attached to the same fixture.

24 A. Armored Cables.—(For construction rules, see No. 48.)

a. Must be continuous from outlet to outlet or to junction boxes, and the armor of the cable must properly enter and be secured to all fittings, and the entire system must be mechanically secured in position.

In case of underground service connections and main runs, this involves running such armored cable continuously into a main cut-out cabinet or gutter surrounding the panel board, as the case may be. (See No. 54.)

b. Must be equipped at every outlet with an *approved* outlet box or plate, as required in conduit work. (See No. 49 A.)

Outlet plates must not be used where it is practicable to install outlet boxes.

The outlet box or plate shall be so installed that it will be flush with the finished surface, and if this surface is broken it shall be repaired so that it will not show any gaps or open spaces around the edge of the outlet box or plate.

In buildings already constructed where the conditions are such that neither outlet box nor plate can be installed, these appliances may be omitted by special permission of the Inspection Department having jurisdiction, provided the armored cable is firmly and rigidly secured in place.

c. Must have the metal armor of the cable permanently and effectively grounded.

It is essential that the metal armor of such systems be joined so as to afford electrical conductivity sufficient to allow the largest fuse of circuit-breaker in the circuit to operate before a dangerous rise in temperature in the system can occur. Armor of cables and gas pipes must be securely fastened in metal outlet boxes so as to secure good electrical connections. Where boxes used for centers of distribution do not afford good electrical connection the armor of the cables must be joined around them by suitable bond wires. Where sections of armored cable are installed without being fastened to the metal structure of buildings or grounded metal piping, they must be bonded together and joined to a permanent and efficient ground connection.

d. When installed in so-called fireproof buildings in course of construction or afterwards if concealed, or where it is exposed to the weather, or in damp places such as breweries, stables, etc., the cable must have a lead covering at least one thirty-second inch in thickness placed between the outer braid of the conductors and the steel armor.

e. Where entering junction boxes, and at all other outlets, etc., must be provided with *approved* terminal fittings which will protect the insulation of the conductors from abrasion, unless such junction or outlet boxes are specially designed and approved for use with the cable.

f. Junction boxes must always be installed in such manner as to be accessible.

g. For alternating current systems must have the two or more conductors of the cable enclosed in one metal armor.

25. Interior Conduits.—(See also Nos. 24 n to p, and 49.)

The object of a tube or conduit is to facilitate the insertion or extraction of the conductors and to protect them from mechanical injury. Tubes or conduits are to be considered merely as raceways, and are not to be relied upon for insulation between wire and wire, or between the wire and the ground.

a. No conduit tube having an internal diameter of less than five-eighths of an inch shall be used. Measurements to be taken inside of metal conduits.

b. Must be continuous from outlet to outlet or to junction boxes, and the conduit must properly enter, and be secured to all fittings and the entire system must be mechanically secured in position.

In case of service connections and main runs, this involves running each conduit continuously into a main cut-out cabinet or gutter surrounding the panel board, as the case may be (see No. 54).

c. Must be first installed as a complete conduit system, without the conductors.

d. Must be equipped at every outlet with an *approved* outlet box or plate (see No. 49 A).

Outlet plates must not be used where it is practicable to install outlet boxes.

The outlet box or plate shall be so installed that it will be flush with the finished surface, and if this surface is broken it shall be repaired so that it will not show any gaps or open spaces around the edge of the outlet box or plate.

In buildings already constructed where the conditions are such that neither outlet box nor plate can be installed, these appliances may be omitted by special permission of the Inspection Department having jurisdiction, providing the conduits ends are bushed and secured.

e. Metal conduits where they enter junction boxes, and at all other outlets, etc., must be provided with *approved* bushings fitted so as to protect wire from abrasion, except when such protection is obtained by the use of *approved* nipples, properly fitted in boxes or devices.

f. Must have the metal of the conduits permanently and effectually grounded.

It is essential that the metal of conduit systems be joined so as to afford electrical conductivity sufficient to allow the largest fuse or circuit breaker in the circuit to operate before a dangerous rise in temperature in the conduit system can occur. Conduits and gas pipes must be securely fastened in metal outlet boxes so as to secure good electrical connection. Where boxes used for centers of distribution do not afford good electrical connection, the conduits must be joined around them by suitable bond wires. Where sections of metal conduit are installed without being fastened to the metal structure of buildings or grounded metal piping, they must be bonded together and joined to a permanent and efficient ground connection.

g. Junction boxes must always be installed in such manner as to be accessible.

h. All elbows or bends must be so made that the conduit or lining of same will not be injured. The radius of the curve of the inner edge of any elbow not to be less than three and one-half inches. Must have not more than the equivalent of four quarter bends from outlet to outlet, the bends at the outlets not being counted.

25 A. Metal Mouldings. (See also Nos. 24 k to m, and 50.)

a. Must be continuous from outlet to outlet, to junction boxes, or approved fittings designed especially for use with metal mouldings, and must at all outlets be provided with approved terminal fittings which will protect the insulation of conductors from abrasion, unless such protection is afforded by the construction of the boxes or fittings.

b. Such moulding where passing through a floor must be carried through an iron pipe extending from the ceiling below to a point five feet above the floor, which will serve as an additional mechanical protection and exclude the presence of moisture often prevalent in such locations.

In residences, office buildings and similar locations where appearance is an essential feature, and where the mechanical strength of the moulding itself is adequate, this ruling may be modified to require the protecting piping from the ceiling below to a point at least three inches above the flooring.

Backing must be secured in position by screws or bolts, the heads of which must be flush with the metal.

The metal of the moulding must be permanently and effectively joined, and must be so installed that adjacent lengths of moulding will be mechanically and electrically secured at all points.

It is essential that the metal of such systems be joined so as to afford electric continuity sufficient to allow the largest fuse in the circuit to operate before a serious rise of temperature in the system can occur. Mouldings and gas pipes be securely fastened in metal outlet boxes, so as to secure good electrical connection. Where boxes used for center of distribution do not afford good electrical connection the metal moulding must be joined around them by suitable bond wires. Sections are installed without being fastened to the metal structure of the building or grounded metal piping, they must be bonded together or joined to a permanent and effective ground connection.

Must be installed so that for alternating systems the two or more of a circuit will be in the same metal moulding.

Is advised that this be done for direct systems also, so that they may be changed to an alternating system at any time, induction troubles preventing such change wires must be in separate mouldings.

i. Fixtures.—(See also Nos. 22 e, 24 v to y.)

Must when supported from the gas piping or any grounded metal of a building be insulated from such piping or metal work by means of approved insulating joints (see No. 59) placed as close as possible to the ceiling walls.

Gas outlet pipes must be protected above the insulating joint by approved insulating tubing, and where outlet tubes are used they must be of sufficient length to extend below the insulating joint, and must be so secured that they will not be pushed down when the canopy is put in place.

Where canopies are placed against plaster walls or ceilings in fireproof buildings, or against metal walls or ceilings, or plaster walls or ceilings on metallic lathing in case of buildings, they must be thoroughly and permanently insulated from such walls or ceilings.

Must have all burrs or fins removed before the conductors are drawn into the fixture.

Must be tested for "contacts" between conductors and fixture, for "short circuits" and for ground connections before it is connected to its conductors.

All fixture arms made of tubing smaller than $\frac{1}{2}$ -inch outside diameter, or the arms of all one-light brackets, must be secured after they are screwed into position by the use of a set-screw properly placed, or by soldering or welding or some equally good method to prevent the arms from becoming loose. Arms must not be made of tubing lighter than No. 18 B. & S. gauge, and must have at screw joints not less than five threads all engaging. This rule does not apply to fixtures or brackets with cast or heavy arms.

j. Sockets.—(For construction rules, see No. 55.)

In rooms where inflammable gases may exist the incandescent lamp socket must be enclosed in a vapor-tight globe, and supported on a hanger, wired with approved rubber-covered wire (see No. 41) soldered directly to the circuit.

Y sockets contain a switch (see No. 17 b).

In damp or wet places "waterproof" sockets must be used. Unless hung on fixtures they must be hung by separate stranded rubber-covered wire not smaller than No. 14 B. & S. gauge, which should preferably be twisted or when the pendant is over three feet long.

These wires must be soldered direct to the circuit wires but supported independently of them.

Key sockets will not be approved if installed over specially inflammable stuff, or where exposed to flyings of combustible material.

Flexible Cord.—

Must have an approved insulation and covering (see No. 45).

Must not be used where the difference of potential between the two conductors is over 300 volts.

Where the above rule does not apply to the grounded circuits in street railway

Must not be used as a support for clusters.

d. Must not be used except for pendants, wiring of fixtures, portable lamps or motors, and portable heating apparatus.

The practice of making the pendants unnecessarily long and then looping them up with cord adjusters is strongly advised against. It offers a temptation to carry about lamps which are intended to hang freely in the air, and the cord adjusters wear off the insulation very rapidly.

For all portable work, including those pendants which are liable to be moved about sufficiently to come in contact with surrounding objects, flexible wires and cables especially designed to withstand this severe service are on the market, and should be used. (See No. 45 f.)

The standard socket is threaded for one-eighth inch pipe, and if it is properly bushed, the reinforced flexible cord will not go into it, but this style of cord may be used with sockets threaded for three-eighths inch pipe, and provided with substantial insulating bushings. The cable to be supported independently of the overhead circuit by a single cleat, and the two conductors then separated and soldered to the overhead wires.

The bulb of an incandescent lamp frequently becomes hot enough to ignite paper, cotton and similar readily ignitable materials, and in order to prevent it from coming in contact with such materials, as well as to protect it from breakage, every portable lamp should be surrounded with a substantial wire guard.

e. Must not be used in show windows except when provided with an approved metal armor.

f. Must be protected by insulating bushings where the cord enters the socket.

g. Must be so suspended that the entire weight of the socket and lamp will be borne by some approved device under the bushing in the socket, and above the point where the cord comes through the ceiling block or rosette, in order that the strain may be taken from the joints and binding screws.

This is usually accomplished by knots in the cord inside the socket and rosette

29. Arc Lamps on Constant-Potential Circuits.—a. Must have a cut-out (see No. 17 a) for each lamp or each series of lamps.

The branch conductors should have a carrying capacity about fifty per cent in excess of the normal current required by the lamp, to provide for heavy current required when lamp is started, or when carbons become stuck without overfusing the wires.

b. Must only be furnished with such resistances or regulators as are enclosed in non-combustible material, such resistances being treated as sources of heat. Incandescent lamps must not be used for this purpose.

c. Must be supplied with globes and protected by spark arresters and wire netting around the globe, as in case of series arc lamps (see Nos. 19 and 58).

Outside arc lamps must be suspended at least eight feet above sidewalks. Inside arc lamps must be placed out of reach or suitably protected.

d. Lamps when arranged to be raised and lowered, either for carboning or other purposes, shall be connected up with stranded conductors from the last point of support to the lamp, when such conductor is larger than No. 14 B. & S. gage.

30. Economy Coils.—a. Economy and compensator coils for arc lamps must be mounted on non-combustible, non-absorptive, insulating supports, such as glass or porcelain, allowing an air space of at least one inch between frame and support, and must in general be treated as sources of heat.

31. Decorative Lighting Systems.—a. Special permission may be given in writing by the Inspection Department having jurisdiction for the temporary installation of approved Systems of Decorative Lighting, provided the difference of potential between the wires of any circuit shall not be over 150 volts and also provided that no group of lamps requiring more than 1,320 watts shall be dependent on one cut-out.

No "System of Decorative Lighting" to be allowed under this rule which is not listed in the Supplement to the National Electrical Code containing list of approved fittings.

31 A. Theater Wiring.—(For rules governing Moving Picture Machine, see No. 65 A.)

All wiring, apparatus, etc., not specifically covered by special rules herein

given must conform to the Standard Rules and Requirements of the National Electrical Code.

In so far as these Rules and Requirements are concerned, the term "theater" shall mean a building or part of a building in which it is designed to make a presentation of dramatic, operatic or other performances or shows for the entertainment of spectators which is capable of seating at least four hundred persons, and which has a stage for such performances that can be used for scenery and other stage appliances.

a. SERVICES.—1. Where source of supply is outside of building, there must be at least two separate and distinct services where practicable, fed from separate street mains, one service to be of sufficient capacity to supply current for the entire equipment of theater, while the other service must be at least of sufficient capacity to supply current for all emergency lights.

By "emergency lights" are meant exit lights and all lights in lobbies, stairways, corridors and other portions of theater to which the public have access which are normally kept lighted during the performance.

2. Where source of supply is an isolated plant within same building, an auxiliary service of at least sufficient capacity to supply all emergency lights must be installed from some outside source, or a suitable storage battery within the premises may be considered the equivalent of such service.

b. STAGE.—1. All permanent construction on stage side of proscenium wall must be *approved* conduit, with the exception of border and switchboard wiring.

2. Switchboards.—Must be made of non-combustible, non-absorptive material, and where accessible from stage level must be protected by an *approved* guard rail to prevent accidental contact with live parts on the board.

3. Footlights.—a. Must be wired in *approved* conduit, each lamp receptacle being enclosed within an *approved* outlet box, the whole to be enclosed in a steel trough, metal to be of a thickness not less than No. 20 gage, or each lamp receptacle may be mounted on or in an iron or steel box so constructed as to enclose all the wires and live parts of receptacles.

b. Must be so wired that no set of lamps requiring more than 1,320 watts will be dependent on one cut-out.

4. Borders.—a. Must be constructed of steel of a thickness not less than No. 20 gage, treated to prevent oxidization, be suitably stayed and supported by a metal framework, and so designed that flanges of reflectors will protect lamps.

b. Must be so wired that no set of lamps requiring more than 1,320 watts will be dependent upon one cut-out.

c. Must be wired in *approved* conduit, each lamp receptacle to be enclosed within an *approved* outlet box, the whole to be enclosed in a steel trough, or each lamp receptacle may be mounted on or in the cover of a steel box so constructed as to enclose all the wires and the live parts of receptacles, metal to be of a thickness not less than No. 20 gage.

d. Must be provided with suitable guards to prevent scenery or other combustible material coming in contact with lamps.

e. Cables must be continuous from stage switchboard to border; conduit construction must be used from switchboard to point where cables must be flexible to permit of the raising and lowering of border, and flexible portion must be enclosed in an *approved* fireproof hose or braid and be suitably supported.

Junction boxes will be allowed on fly floor and rigging loft in existing theaters where the wiring has been completed and approved by Inspection Department having jurisdiction.

f. For the wiring of the border proper, wire with slow burning insulation should be used.

g. Must be suspended with wire rope, same to be insulated from border by at least two *approved* strain insulators properly inserted.

5. Stage Pockets.—Must be of approved type controlled from switchboard, each receptacle to be of not less than fifty amperes rating, and each receptacle to be wired with a separate circuit to its full capacity.

6. Proscenium Side Lights.—Must be so installed that they cannot interfere with the operation of or come in contact with curtain.

7. *Scene Docks*.—Where lamps are installed in Scene Docks, they must be so located and installed that they will not be liable to mechanical injury.

8. *Curtain Motors*.—Must be of ironclad type and installed so as to conform to the requirements of the National Electrical Code. (See No. 8.)

9. *Control for Stage Flues*.—

a. In cases where dampers are released by an electric device, the electric circuit operating same must be normally closed.

b. Magnet operating damper must be wound to take full voltage of circuit by which it is supplied, using no resistance device, and must not heat more than normal for apparatus of similar construction. It must be located in loft above scenery, and be installed in a suitable iron box with a tight self-closing door.

c. Such dampers must be controlled by at least two standard single pole switches mounted within *approved* iron boxes provided with self-closing doors without lock or latch, and located, one at the Electrician's station, and others as designated by the Inspection Department having jurisdiction.

c. *DRESSING ROOMS*.

1. Must be wired in *approved* conduit, except that in existing buildings where it is impracticable to install *approved* conduit, *approved* armored cable may be used, provided it is installed in accordance with No. 24 A.

2. All pendant lights must be equipped with *approved* reinforced cord or cable.

3. All lamps must be provided with *approved* guards.

d. *PORTABLE EQUIPMENTS*.

1. *Arc lamps* used for stage effects must conform to the following requirements:—

a. Must be constructed entirely of metal except where the use of *approved* insulating material is necessary.

b. Must be substantially constructed, and so designed as to provide for proper ventilation, and to prevent sparks being emitted from lamps when same is in operation, and mica must be used for frame insulation.

c. Front opening must be provided with a self-closing hinged door frame in which wire gauze or glass must be inserted, excepting lens lamps, where the front may be stationary, and solid door be provided on back or side.

d. Must be provided with a one-sixteenth-inch iron or steel guard having a mesh not larger than one inch, and be substantially placed over top and upper half of sides and back of lamp frame; this guard to be substantially riveted to frame of lamp, and to be placed at a distance of at least two inches from the lamp frame.

e. Switch on standard must be so constructed that accidental contact with any live portion of same will be impossible.

f. All stranded connections in lamp and at switch and rheostat must be provided with *approved* lugs.

g. Rheostat, if mounted on standard, must be raised to a height of at least three inches above floor line, and in addition to being properly enclosed must be surrounded with a substantially attached metal guard having a mesh not larger than one square inch, which guard is to be kept at least one inch from outside frame of rheostat.

h. A competent operator must be in charge of each arc lamp, except that one operator may have charge of two lamps when they are not more than ten feet apart, and are so located that he can properly watch and care for both lamps.

2. *Bunches*.—a. Must be substantially constructed of metal, and must not contain any exposed wiring.

b. The cable feeding same must be bushed in an *approved* manner where passing through the metal, and must be properly secured to prevent any mechanical strain from coming on the connection.

3. *Strips*.—a. Must be constructed of steel of a thickness not less than No. 20 gage, treated to prevent oxidization, and suitably stayed and supported by metal framework.

b. Cable feeding must be bushed in an *approved* manner where passing through the metal, and must be properly secured to prevent any mechanical strain from coming on the connections.

4. *Portable Plugging Boxes.*—Must be constructed so that no current carrying part will be exposed, and each receptacle must be protected by *approved* fuses mounted on slate or marble bases and enclosed in a fireproof cabinet equipped with self-closing doors. Each receptacle must be constructed to carry thirty amperes without undue heating, and the bus-bars must have a carrying capacity equivalent to the current required for the total number of receptacles, allowing thirty amperes to each receptacle, and *approved* lugs must be provided for the connection of the master cable.

5. *Pin Plug Conductors*—a. When of *approved* type may be used to connect *approved* portable lights and appliances.

b. Must be so installed that the "female" part of plug will be on the live end of cable, and must be so constructed that tension on the cable will not cause any serious mechanical strain on the connections.

6. *Lights on Scenery.*—Where brackets are used they must be wired entirely on the inside, fixture stem must come through to the back of the scenery and end of stem be properly bushed.

7. *String or Festoon Lights.*—Wiring for same should be *approved* cable, joints where taps are taken from same for lights to be properly made, soldered and taped, and where lamps are used in lanterns or similar devices lamps must be provided with *approved* guards. Where taps are taken from cable, they should be so staggered that joints of different polarity will not come immediately opposite each other and must be properly protected from strain.

8. *Special Electrical Effects.*—Where devices are used for producing special effects such as lightning, waterfalls, etc., the apparatus must be so constructed and located that flames, sparks, etc., resulting from the operation cannot come in contact with combustible material.

e. AUDITORIUM.—1. All wiring must be installed in *approved* conduit, except that in existing buildings where it is impracticable to install *approved* conduit, *approved* armored cable may be used, provided it is installed in accordance with No. 24 A.

2. All fuses used in connection with lights illuminating all parts of the house used by the audience must be installed in fireproof enclosures so constructed that there will be a space of at least six inches between the fuses and the sides and face of enclosure.

3. Exit lights must not have more than one set of fuses between same and service fuses.

4. Exit lights and all lights in halls, corridors or any other part of the building used by the audience, except the general auditorium lighting, must be fed independently of the stage lighting, and must be controlled only from the lobby or other convenient place in front of the house.

5. Every portion of the theater devoted to the use or accommodation of the public, also all outlets leading to the streets and including all open courts, corridors, stairways, exits and emergency exit stairways, should be well and properly lighted during every performance, and the same should remain lighted until the entire audience has left the premises.

32. *Car Wiring and Equipment of Cars.*—a. *Protection of Car Body, etc.*—1. Under side of car bodies to be protected by *approved* fire-resisting, insulating material, not less than $\frac{1}{4}$ -inch in thickness, or by sheet iron or steel, not less than .04-inch in thickness, as specified in Section a, 2, 3 and 4. This protection to be provided over all electrical apparatus, such as motors with a capacity of over 75 H. P. each, resistances, contactors, lightning arresters, air-brake motors, etc., and also where wires are run, except that protection may be omitted over wires designed to carry 25 amperes or less if they are encased in metal conduit.

2. At motors of over 75 H. P. each, fire-resisting material or sheet iron or steel to extend not less than 8 inches beyond all edges of openings in motors, and not less than 6 inches beyond motor leads on all sides.

3. Over resistances, contactors, and lightning arresters, and other electrical apparatus, excepting when amply protected by their casing, fire-resisting material or sheet iron or steel to extend not less than 8 inches beyond all edges of the devices.

4. Over conductors, not encased in conduit, and conductors in conduit

when designed to carry over 25 amperes, unless the conduit is so supported as to give not less than $\frac{1}{4}$ -inch clear air space between the conduit and the car, fire-resisting material or sheet iron or steel to extend at least 6 inches beyond conductors on either side.

The fire-resisting insulating material or sheet iron or steel may be omitted over cables made up of flameproof braided outer covering when surrounded by $\frac{1}{4}$ -inch flameproof covering, as called for by Section 1, 4.

5. In all cases fireproof material or sheet iron or steel to have joints well fitted, to be securely fastened to the sills, floor timbers and cross braces and to have the whole surface treated with a waterproof paint.

6. Cut-out and switch cabinets to be substantially made of hard wood. The entire inside of cabinet to be lined with not less than $\frac{1}{4}$ -inch fire-resisting insulating material which shall be securely fastened to the woodwork, and after the fire-resisting material is in place the inside of the cabinet shall be treated with a waterproof paint.

b. *Wires, Cables, etc.*—1. All conductors to be stranded, the allowable carrying capacity being determined by Table "A" of No. 16, except that motor, trolley and resistance leads shall not be less than No. 7 B. & S. gage, heater circuits not less than No. 12 B. & S. gage, and lighting and other auxiliary circuits not less than No. 14 B. & S. gage.

The current used in determining the size of motor, trolley and resistance leads shall be the per cent of the full load current, based on one hour's run of motor, as given by the following table:—

Size of each Motor.	Motor Leads.	Trolley Leads.	Resistance Leads.
75 H. P. or less.....	50%	40%	15%
Over 75 H. P.	45%	35%	15%

Fixture wire complying with No. 46 will be permitted for wiring *approved* cluster.

2. To have an insulation and braid as called for by No. 41 for wires carrying currents of the same potential.

3. When run in metal conduit, to be protected by an additional braid as called for by No. 47.

Where conductors are laid in conduit, not being drawn through, the additional braid will not be required.

4. When not in conduit, in *approved* moulding, or in cables surrounded by $\frac{1}{4}$ -inch flameproof covering, must comply with the requirements of No. 41 (except that tape may be substituted for braid) and be protected by an additional flameproof braid, at least 1-32 of an inch in thickness, the outside being saturated with a preservative flameproof compound.

This rule will be interpreted to include the leads from the motors.

5. Must be so spliced or joined as to be both mechanically and electrically secure without solder. The joints must then be soldered and covered with an insulation equal to that on the conductors.

Joints made with *approved* splicing devices and those connecting the leads at motors, plows or third-rail shoes need not be soldered.

6. All connections of cables to cut-outs, switches and fittings, except those to controller connection boards, when designed to carry over 25 amperes, must be provided with lugs or terminals soldered to the cable, and securely fastened to the device, by bolts, screws or by clamping; or, the end of the cable, after the insulation is removed, shall be dipped in solder and be fastened into the device by at least two set screws having check nuts.

All connections for conductors to fittings, etc., designed to carry less than 25 amperes, must be provided with up-turned lugs that will grip the conductor between the screw and the lug, the screws being provided with flat washers; or by block terminals having two set screws, and the end of the conductors must be dipped in solder. Soldering, in addition to the connection of the binding screws, is strongly recommended, and will be insisted on when above requirements are not complied with.

This rule will not be construed to apply to circuits where the maximum potential is not over 25 volts, and current does not exceed 5 amperes.

c. *Cut-outs, Circuit-Breakers and Switches.*—1. All cut-outs and switches having exposed live metal parts to be located in cabinets. Cut-outs and switches, not in iron boxes or in cabinets, shall be mounted on not less than $\frac{1}{4}$ -inch fire-resisting insulating material, which shall project at least $\frac{1}{4}$ -inch beyond all sides of the cut-out or switch.

2. Cut-outs to be of the *approved* cartridge or *approved* blow-out type.

3. All switches controlling circuits of over 5 ampere capacity shall be of *approved* single-pole, quick-break or *approved* magnetic blow-out type. Switches controlling circuits of 5 ampere or less capacity may be of the *approved* single-pole, double-break, snap type.

4. Circuit breakers to be of *approved* type.

5. Circuits must not be fused above their safe carrying capacity.

6. A cut-out must be placed as near as possible to the current collector, so that the opening of the fuse in this cut-out will cut off all current from the car.

When cars are operated by metallic return circuits, the circuit breakers connected to both sides of the circuit, no fuses in addition to the circuit breakers will be required.

d. *Conduit*.—[When from the nature of the case, or on account of the size of the conductors, the ordinary pipe and junction box construction is not permissible, a special form of conduit system may be used, provided the general requirements as given below are complied with.]

1. Metal conduits, outlet and junction boxes to be constructed in accordance with Nos. 49 and 49 A, except that conduit for lighting circuits need not be over 5/16 inch internal diameter and 1/2-inch external diameter, and for heating and air motor circuits need not be over 1/2-inch internal diameter and 9/16-inch external diameter, and all conduits where exposed to dampness must be water tight.

2. Must be continuous between and be firmly secured into all outlet or junction boxes and fittings, making a thorough mechanical and electrical connection between same.

3. Metal conduits, where they enter all outlet or junction boxes and fittings, must be provided with *approved* bushings fitted so as to protect cables from abrasion.

4. Except as noted in Section i, 2, must have the metal of the conduit permanently and effectively grounded.

5. Junction and outlet boxes must be installed in such a manner as to be accessible.

6. All conduits, outlets or junction boxes and fittings to be firmly and substantially fastened to the framework of the car.

e. *Moulding*.—1. To consist of a backing and a capping and to be constructed of fire-resisting insulating material, except that it may be made of hard wood where the circuits which it is designed to support are normally not exposed to moisture.

2. When constructed of fire-resisting insulating material, the backing shall not be less than 1/2-inch in thickness and be of a width sufficient to extend not less than 1 inch beyond conductors at sides.

The capping, to be not less than 1/2-inch in thickness shall cover and extend at least 1/2-inch beyond conductors on either side.

The joints in the moulding shall be mitered to fit close, the whole material being firmly secured in place by screws or nails, and treated on the inside and outside with a waterproof paint.

When fire-resisting moulding is used over surfaces already protected by 1/2-inch fire-resisting insulating material no backing will be required.

3. Wooden mouldings must be so constructed as to thoroughly encase the wire and provide a thickness of not less than 1/2-inch at the sides and back of the conductors, the capping being not less than 3/16-inch in thickness. Must have both outside and inside two coats of waterproof paint.

The backing and the capping shall be secured in place by screws.

f. *Lighting and Lighting Circuits*.—1. Each outlet to be provided with an *approved* porcelain receptacle, or an *approved* cluster. No lamp of over 82 candle power to be used.

2. Circuits to be run in *approved* metal conduit, or *approved* moulding.

3. When metal conduit is used, except for sign lights, all outlets to be provided with *approved* outlet boxes.

4. At outlet boxes, except where *approved* clusters are used, porcelain receptacles to be fastened to the inside of the box, and the metal cover to have an insulating bushing around opening for the lamp.

When *approved* clusters are used, the cluster shall be thoroughly insulated from the metal conduit, being mounted on a block of hard wood or fire-resisting insulating material.

5. Where conductors are run in moulding the porcelain receptacles or cluster to be mounted on blocks of hard wood or of fireproof insulating material.

g. Heaters and Heating Circuits.—1. Heaters to be of *approved* type.

2. Panel heaters to be so constructed and located that when heaters are in place all current-carrying parts will be at least 4 inches from all woodwork.

Heaters for cross seats to be so located that current-carrying parts will be at least 6 inches below under side of seat, unless under side of seat is protected by not less than $\frac{1}{4}$ -inch fire-resisting insulating material, of .04 inch sheet metal with 1 inch air space over same, when the distance may be reduced to 3 inches.

2. Circuits to be run in *approved* metal conduit, or in *approved* moulding, or if the location of conductors is such as will permit an air space of not less than 2 inches on all sides except from the surface wired over, they may be supported on porcelain knobs or cleats, provided the knobs or cleats are mounted on not less than $\frac{1}{4}$ -inch fire-resisting insulating material extending at least 3 inches beyond conductors at either side, the supports raising the conductors not less than $\frac{1}{4}$ -inch from the surface wired over, and being not over 12 inches apart.

h. Air Pump Motor and Circuits.—1. Circuits to be run in *approved* metal conduit or in *approved* moulding, except that when run below the floor of the car they may be supported on porcelain knobs or cleats, provided the supports raise the conductor at least $\frac{1}{4}$ -inch from the surface wired over and are not over 12 inches apart.

2. Automatic control to be enclosed in *approved* metal box. Air pump and motor, when enclosed, to be in *approved* metal box or a wooden box lined with metal of not less than 1/32 inch in thickness.

When conductors are run in metal conduit the boxes surrounding automatic control and air pump and motor may serve as outlet boxes.

1. Main Motor Circuits and Devices.—1. Conductors connecting between trolley stand and main cut-out or circuit breakers in hood to be protected where wires enter car to prevent ingress of moisture.

2. Conductors connecting between third rail shoes on same truck, to be supported in an *approved* fire-resisting insulating moulding, or in *approved* iron conduit supported by soft rubber or other *approved* insulating cleats.

3. Conductors on the under side of the car, except as noted in Section i, 4, to be supported in accordance with one of the following methods:—

a. To be run in *approved* metal conduit, junction boxes being provided where branches in conduit are made, and outlet boxes where conductors leave conduit.

b. To be run in *approved* fire-resisting insulating moulding.

c. To be supported by insulating cleats, the supports being not over 12 inches apart.

4. Conductors with flameproof braided outer covering, connecting between controllers at either end of car, or controllers and contactors, may be run as a cable, provided the cable where exposed to the weather is encased in a canvas hose or canvas tape, thoroughly taped or sewed at ends and where taps from the cable are made, and the hose or tape enters the controllers.

Conductors with or without flameproof braided outer covering connecting between controllers at either end of the car, or controllers and contactors, may be run as a cable, provided the cable throughout its entire length is surrounded by $\frac{1}{4}$ -inch flameproof covering, thoroughly taped or sewed at ends, or where taps from cable are made, and the flameproof covering enters the controllers.

Cables, where run below floor of car, may be supported by *approved* insulating straps or cleats. Where run above floor of car, to be in a metal conduit or wooden box painted on the inside with not less than two coats of flameproof paint, and where this box is so placed that it is exposed to water, as by washing of the car floor, attention should be given to making the box reasonably waterproof.

Canvas hose or tape, or flameproof material surrounding cables after conductors are in same, to have not less than two coats of waterproof insulating material.

5. Motors to be so drilled that, on double truck cars, connecting cables can leave motor on side nearest to kingbolt.

6. Resistances to be so located that there will be at least 6-inch air space between resistances proper and fire-resisting material of the car. To be mounted on iron supports, being insulated by non-combustible bushings or washers, or the iron supports shall have at least 2 inches of insulating surface between them and metal work of car, or the resistances may be mounted on hard wood bars, supported by iron stirrups, which shall have not less than 2 inches of insulating surface between foot of resistance and metal stirrup, the entire surface of the bar being covered with at least $\frac{1}{4}$ -inch fire-resisting insulating material.

The insulation of the conductor, for about 6 inches from terminal of the resistance, should be replaced, if any insulation is necessary, by a porcelain bushing or asbestos sleeve.

7. Controllers to be raised above platform of car by not less than 1-inch hard wood block, the block being fitted and painted to prevent moisture working in between it and the platform.

j. Lightning Arresters.—1. To be preferably located to protect all auxiliary circuits in addition to main motor circuits.

2. The ground conductor shall be not less than No. 6 B. & S. gage, run with as few kinks and bends as possible, and be securely grounded.

k. General Rules.—1. When passing through floors, conductors or cables must be protected by *approved* insulating bushings, which shall fit the conductor or cable as closely as possible.

2. Moulding should never be concealed except where readily accessible. Conductors should never be tacked into moulding.

3. Short bends in conductors should be avoided where possible.

4. Sharp edges in conduit or in moulding must be smoothed to prevent injury to conductors.

33. Car Houses.—**a.** The trolley wires must be securely supported on insulating hangers.

b. The trolley hangers must be placed at such a distance apart that, in case of a break in the trolley wire, contact with the floor cannot be made.

c. Must have an emergency cut-out switch located at a proper place outside of the building, so that all the trolley wires in the building may be cut out at one point, and line insulators must be installed, so that when this emergency switch is open, the trolley wire will be dead at all points within 100 feet of the building. The current must be cut out of the building when not needed for use in the building.

This may be done by the emergency switch, or if preferred, a second switch may be used that will cut out all current from the building, but which need not cut out the trolley wire outside as would be the case with the emergency switch.

d. All lamps and stationary motors must be installed in such a way that one main switch may control the whole of each installation, lighting and power, independently of the main cut-out switch called for in Section c.

e. Where current for lighting and stationary motors is from a grounded trolley circuit, the following special rules to apply:—

1. Cut-outs must be placed between the non-grounded side and lights or motors they are to protect. No set or group of incandescent lamps requiring over 2,000 watts must be dependent upon one cut-out.

2. Switches must be placed between non-grounded side and lights and motors they are to protect.

3. Must have all rails bonded at each joint with a conductor having a carrying capacity at least equivalent to No. 00 B. & S. gage annealed copper wire, and all rails must be connected to the outside ground return circuit by not less than No. 00 B. & S. gage copper wire or by equivalent bonding through the track. All

Lighting and stationary motor circuits must be thoroughly and permanently connected to the rails or to the wire leading to the outside ground return circuit.

f. All pendant cords and portable conductors will be considered as subject to hard usage (see 45, f).

g. Must, except as provided in Section e, have all wiring and apparatus installed in accordance with the rules for constant potential systems.

h. Must not have any system of feeder distribution centering in the building.

i. Cars must not be left with the trolley in electrical connection with the trolley wire.

34. Lighting and Power from Railway Wires.—a. *Must not be permitted, under any pretense, in the same circuit with trolley wires with a ground return, except in electric railway cars, electric car houses and their power stations; nor shall the same dynamo be used for both purposes.*

CONSTANT-HIGH-POTENTIAL SYSTEMS.

550 TO 3,500 VOLTS.

Any circuit attached to any machine or combination of machines which develops a difference of potential between any two wires, of over 550 volts and less than 3,500 volts, shall be considered as a high-potential circuit, and as coming under that class, unless an approved transforming device is used, which cuts the difference of potential down to 550 volts or less.

(See note following first paragraph under Low-Potential systems, page 1408.)

35. Wires.—(See also Nos. 14, 15 and 16.) a. Must have an *approved* rubber-insulating covering (see No. 41).

b. Must be always in plain sight and never encased, except as provided for in No. 8 b, or where required by the Inspection Department having jurisdiction.

c. Must (except as provided for in No. 8 b), be rigidly supported on glass or porcelain insulators, which raise the wire at least 1 inch from the surface wired over, and must be kept about 8 inches apart.

Rigid supporting requires under ordinary conditions, where wiring along flat surfaces, supports at least about every 4½ feet. If the wires are unusually liable to be disturbed, the distance between supports should be shortened.

In buildings of mill construction, mains of not less than No. 8 B. & S. gage, where not liable to be disturbed, may be separated about ten inches and run from timber to timber, not breaking around, and may be supported at each timber only.

d. Must be protected on side walls from mechanical injury by a substantial boxing, retaining an air space of 1 inch around the conductors, closed at the top (the wires passing through bushed holes) and extending not less than 7 feet from the floor. When crossing floor timbers, in cellars, or in rooms where they might be exposed to injury, wires must be attached by their insulating supports to the under side of a wooden strip not less than ½-inch in thickness.

For general suggestions on protection, see note under No. 24 e. See also note under No. 18 e.

36. Transformers.—(When permitted inside buildings under No. 12.) (For construction rules see No. 62.) (See also Nos. 13 and 19 A.)

Transformers must not be placed inside of buildings without special permission from the Inspection Department having jurisdiction.

a. Must be located as near as possible to the point at which the primary wires enter the building.

b. Must be placed in an enclosure constructed of fire-resisting material; the enclosure to be used only for this purpose, and to be kept securely locked, and access to the same allowed only to responsible parties.

c. Must be thoroughly insulated from the ground, or permanently and effectually grounded, and the enclosure in which they are placed must be practically air-tight, except that it must be thoroughly ventilated to the outdoor air, if possible through a chimney or flue. There should be at least 6 inches air space on all sides of the transformer.

37 Series Lamps.—a. No multiple-series or series-multiple system of lighting will be approved.

b. Must not, under any circumstances, be attached to gas fixtures.

CONSTANT EXTRA-HIGH-POTENTIAL SYSTEMS.

OVER 3,500 VOLTS.

Any circuit attached to any machine or combination of machines which develops a difference of potential, between any two wires, of over 3,500 volts, shall be considered as an extra-high-potential circuit, and as coming under that class, unless an approved transforming device is used, which cuts the difference of potential down to 3,500 volts or less.

38. Primary Wires.—a. Must not be brought into or over buildings, except power stations and sub-stations.

39. Secondary Wires.—a. Must be installed under rules for high-potential systems when their immediate primary wires carry a current at a potential of over 3,500 volts, unless the primary wires are installed in accordance with the requirements as given in No. 12 A or are entirely underground, within city, town and village limits.

Class D.—FITTINGS, MATERIALS AND DETAILS OF CONSTRUCTION.

(LIGHT, POWER AND HEAT. FOR SIGNALING SYSTEMS, SEE CLASS E.)

ALL SYSTEMS AND VOLTAGES.

The following rules are but a partial outline of requirements. Devices or materials which fulfill the conditions of these requirements and no more, will not necessarily be acceptable. All fittings and materials should be submitted for examination and test before being introduced for use.

INSULATED WIRES—RULES 40 TO 43.

40. General Rules.—a. Copper for insulated solid conductors of No. 4 B. & S. gage and smaller must not vary in diameter more than .002 of an inch from the standard. On solid sizes larger than No. 4 B. & S. gage the diameter shall not vary more than one per cent from the specified standard. The conductivity of solid conductors shall not be less than 97% of that of pure copper of the specified size.

In all stranded conductors the sum of the circular mils of the individual wires, shall not be less than the normal circular mils of the strand by more than one and one-half per cent. The conductivity of the individual wires in a strand shall not be less than is given in the following table:—

Number.	Per cent.	Number.	Per cent.
14 and larger.	97.0	23	95.2
15	96.8	24	95.0
16	96.6	25	94.8
17	96.4	26	94.6
18	96.2	27	94.4
19	96.0	28	94.2
20	95.8	29	94.0
21	95.6	30	93.8
22	95.4		

The Standard for diameters and mileages shall be that adopted by the American Institute of Electrical Engineers.

b. Wires and cables of all kinds designed to meet the following specifications must have a distinctive marking the entire length of the coil so that they may be readily identified in the field. They must also be plainly tagged or marked as follows:—

1. The maximum voltage at which the wire is designed to be used.
2. The words "National Electrical Code Standard."

3. Name of the manufacturing company and, if desired, trade name of the wire.

4. Month and year when manufactured.

Wires described under Nos. 42, 43 and 44 need not have the distinctive marking, but are to be tagged.

41. **Rubber-Covered Wire.**—a. Copper for conductors must be thoroughly tinned.

Insulation for Voltages, 0 to 600 inclusive.—b. Must be of rubber or other approved substances, homogeneous in character, adhering to the conductor and of a thickness not less than that given in the following table:—

B. & S. Gage.	Thickness.
18 to 16.....	1-32 inch.
15 to 8.....	3-64 "
7 to 2.....	1-16 "
1 to 0000.....	5-64 "

Circular Mills.

250,000 to 500,000.....	3-32 "
500,000 to 1,000,000.....	7-64 "
Over 1,000,000.....	1-8 "

Measurements of insulating wall are to be made at the thinnest portion of the dielectric.

c. The completed coverings must show an insulation resistance of at least 100 megohms per mile during thirty days' immersion in water at 70° Fahrenheit (21° Centigrade).

d. Each foot of the completed covering must show a dielectric strength sufficient to resist throughout five minutes the application of an electro-motive force proportionate to the thickness of insulation in accordance with the following table:—

Thickness in 64ths inches.	Breakdown Test on 1 foot.	Thickness in 64ths inches.	Breakdown Test on 1 foot.
1	3,000 Volts A. C.	7	16,500 Volts A. C.
2	6,000 " "	8	18,000 " "
3	9,000 " "	10	21,000 " "
4	11,000 " "	12	23,500 " "
5	13,000 " "	14	26,000 " "
6	15,000 " "	16	28,000 " "

The source of alternating electro-motive force shall be a transformer of at least one kilowatt capacity. The application of the electro-motive force shall first be made at 4,000 volts for five minutes, and then the voltage increased by steps of not over 3,000 volts, each held for five minutes, until the rupture of the insulation occurs. The tests for dielectric strength shall be made on a sample of wire which has been immersed in water for seventy-two hours. One foot of the wire under test is to be submerged in a conducting liquid held in a metal trough, one of the transformer terminals being connected to the copper of the wire and the other to the metal of the trough.

Insulations for Voltages, 601 to 3,500 inclusive.—e. The thickness of the insulating wall must not be less than that given in the following table:—

B. & S. Gage.	Thickness.
14 to 1.....	3-32 inch.
0 to 0000.....	3-32 " covered by tape or braid.
Circular Mills.	
250,000 to 500,000.....	3-32 " " " "
Over 500,000.....	1-8 " " " "

f. The requirements as to insulation and breakdown resistance for wires for low-potential systems shall apply, with the exception that an insulation resistance of not less than 300 megohms per mile shall be required.

Insulations for Voltages Over 3,500.—g. Wire for arc light circuits exceeding 3,500 volts potential must have an insulating wall not less than $\frac{1}{4}$ of an inch in thickness, and shall withstand a breakdown test of at least 23,500 volts, and have an insulation of at least 500 megohms per mile.

The tests on this wire to be made under the same conditions as for low-potential wires.

Specifications for insulations for alternating currents exceeding 3,500 volts have been considered, but on account of the somewhat complex conditions of such work, it has so far been deemed inexpedient to specify general insulations for this use.

General.—h. The rubber compound or other approved substance used as insulation must be sufficiently elastic to permit all wires smaller than No. 7 B. & S. gage and larger than No. 11 B. & S. gage to be bent without injury to the insulation around a cylinder twice the diameter of the insulated wire measured over the outer covering. All wires No. 11 B. & S. gage and smaller to be bent without injury to the insulation around a cylinder equal to the diameter of the insulated wire measured over the outer covering.

i. All the above insulations must be protected by a substantial braided covering properly saturated with a preservative compound. This covering must be sufficiently strong to withstand all the abrasions likely to be met with in practice, and must substantially conform to approved samples submitted by the manufacturer.

42. Slow-burning Weatherproof Wire.—[This wire is not as burnable as "weatherproof" nor as subject to softening under heat. It is not suitable for outside work.]

a. The insulation must consist of two coatings, one to be fireproof in character and the other to be weatherproof. The fireproof coating must be on the outside and must comprise about 6/10 of the total thickness of the wall. The completed covering must be of a thickness not less than that given in the following table:—

B. & S. Gage.	Thickness.
14 to 8.....	3-64 inch.
7 to 2.....	1-16 "
1 to 0000.....	5-64 "
Circular Mils.	
250,000 to 500,000.....	3-32 "
500,000 to 1,000,000.....	7-64 "
Over 1,000,000.....	1-8 "

Measurements of insulating wall are to be made at the thinnest portion.

b. The fireproof coating shall be of the same kind as that required for "slow-burning wire," and must be finished with a hard, smooth surface.

c. The weatherproof coating shall consist of a stout braid, applied and treated as required for "weatherproof wire."

43. Slow-burning Wire.—a. The insulation must consist of three braids of cotton or other thread, all the interstices of which must be filled with the fireproofing compound or with material having equivalent resisting and insulating properties. The outer braid must be specially designed to withstand abrasion, and its surface must be finished smooth and hard. The completed covering must be of a thickness not less than that given in the table under No. 42 a.

The solid constituent of the fireproofing compound must not be susceptible to moisture, and must not burn even when ground in an oxidizable oil, making a compound, which, while proof against fire and moisture, at the same time has considerable elasticity, and which when dry will suffer no change at a temperature of 250° Fahrenheit (121° Centigrade), and which will not burn at even a higher temperature.

This is practically the old so-called "underwriters" insulation. It is especially useful in hot, dry places where ordinary insulations would perish, and where wires are bunched, as on the back of a large switchboard or in a wire tower, so that the accumulation of rubber insulation would result in an objectionably large mass of highly inflammable material.

44 Weatherproof Wire.—a. The insulating covering shall consist of at least three braids, all of which must be thoroughly saturated with a dense moisture-proof compound, applied in such a manner as to drive any atmospheric moisture from the cotton braiding, thereby securing a covering to a great degree waterproof and of high insulating power. This compound must retain its elasticity at 0° Fahrenheit (minus 18° Centigrade), and must not drip at 160° Fahrenheit (71° Centigrade). The thickness of insulation must not be less than that given in the table under No. 42 a, and the outer surface must be thoroughly slicked down.

This wire is for use outdoors, where moisture is certain and where fire-proof qualities are not necessary.

45. Flexible Cord.—(For installation rules, see No. 28). a. Must, except as required for portable heating apparatus (see Section g), be made of stranded copper conductors, each strand to be not larger than No. 26 or smaller than No. 30 B. & S. gage, and each stranded conductor must be covered by an *approved* insulation and protected from mechanical injury by a tough, braided outer covering.

For Pendant Lamps.—[In this class is to be included all flexible cord which, under usual conditions, hangs freely in air, and which is not likely to be moved sufficiently to come in contact with surrounding objects.

It should be noted that pendant lamps provided with long cords, so that they can be carried about or hung over nails, or on machinery, etc., are not included in this class, even though they are usually allowed to hang freely in air.]

b. Each stranded conductor must have a carrying capacity equivalent to not less than a No. 18 B. & S. gage wire.

c. The covering of each stranded conductor must be made up as follows:—

1. A tight, close wind of fine cotton.
2. The insulation proper, which shall be waterproof.
3. An outer cover of silk or cotton.

The wind of cotton tends to prevent a broken strand puncturing the insulation and causing a short circuit. It also keeps the rubber from corroding the copper.

d. The insulation must be solid, at least $1/32$ of an inch thick, and must show an insulation resistance of 50 megohms per mile throughout two weeks immersion in water at 70° Fahrenheit (21° Centigrade), and stand the tests prescribed for low-tension wires as far as they apply.

e. The outer protecting braiding should be so put on and sealed in place that when cut it will not fray out, and where cotton is used it should be impregnated with a flameproof paint which will not have an injurious effect on the insulation.

For Portables.—[In this class is included all cord used on portable lamps, small portable motors, or any device which is liable to be carried about.]

f. Flexible cord for portable use, except in offices, dwellings or similar places, where cord is not liable to rough usage and where appearance is an essential feature, must meet all the requirements for flexible cord for "pendant lamps," both as to construction and thickness of insulation, and in addition must have a tough, braided cover over the whole. There must also be an extra layer of rubber between the outer cover and flexible cord, and in moist places the outer cover must be saturated with a moisture-proof compound, thoroughly slicked down, as required for "weatherproof wire." (See No. 44.) In offices, dwellings, or in similar places where cord is not liable to rough usage and where appearance is an essential feature, flexible cord for portable use must meet all of the requirements for flexible cord for "pendant lamps," both as to construction and thickness of insulation, and in addition must have a tough, braided cover over the whole, or, providing there is an extra layer of rubber between the flexible cord and the outer cover, the insulation proper on each stranded conductor of cord may be $1/64$ of an inch in thickness instead of $1/32$ of an inch as required for pendant cords.

Flexible cord for portable use may, instead of the outer coverings described above, have an approved metal flexible armor.

For Portable Heating Apparatus.—[Applies to all smoothing and sad irons, and to any other device requiring over 250 watts.]

g. Must be made up as follows:—

1. Conductors must be of braided copper, each strand not to be larger than No. 30 or smaller than No. 36 B. & S. gage.

When conductors have a greater carrying capacity than No. 12 B. & S. gage they may be braided or stranded with each strand as large as No. 28 B. & S. gage. If stranded, there must be a tight, close wind of cotton between the conductor and the insulation.

2. An insulating covering of rubber or other *approved* material not less than $1/64$ inch in thickness.

3. A braided covering of not less than $1/32$ inch thick, composed of best quality long fiber asbestos, containing not over five per cent vegetable fiber.

4. The several conductors comprising the cord to be enclosed by an outer reinforcing covering not less than 1/64 inch thick, especially designed to resist abrasion, and so treated as to prevent the cover from fraying.

46. **Fixture Wire.**—(For installation rules, see No. 24, v to y.) a. May be made of solid or stranded conductors, with no strands smaller than No. 30 B. & S. gage, and must have a carrying capacity not less than that of a No 18 B. & S. gage wire.

b. Solid conductors must be thoroughly tinned. If a stranded conductor is used, it must be covered by a tight, close wind of fine cotton.

c. Must have a solid rubber insulation of a thickness not less than 1/32 of an inch for Nos. 18 to 16 B. & S. gage, and 3/64 of an inch for Nos. 14 to 8 B. & S. gage, except that in arms of fixtures not exceeding 24 inches in length and used to supply not more than one 16-candle-power lamp or its equivalent, which are so constructed as to render impracticable the use of a wire with 1/32 of an inch in thickness of rubber insulation, a thickness of 1/64 of an inch will be permitted.

d. Must be protected with a covering at least 1/64 of an inch in thickness, sufficiently tenacious to withstand the abrasion of being pulled into the fixture, and sufficiently elastic to permit the wire to be bent around a cylinder with twice the diameter of the wire without injury to the braid.

e. Must successfully withstand the tests specified in Nos. 41 c and 41 d.

In wiring certain designs of show-case fixtures, ceiling bulls-eyes and similar appliances in which the wiring is exposed to temperatures in excess of 120° Fahrenheit (49° Centigrade), from the heat of lamps, slow-burning wire may be used (see No. 43). All such forms of fixtures must be submitted for examination, test and approval before being introduced for use.

47. **Conduit Wire.**—(For installation rules, see No. 24 n to p.)

a. Single wire for lined conduits must comply with the requirements of No. 41. For unlined conduits it must comply with the same requirements (except that tape may be substituted for braid) and in addition there must be a second outer fibrous covering, at least 1/32 of an inch in thickness and sufficiently tenacious to withstand the abrasion of being hauled through the metal conduit.

b. For twin or duplex wires in lined conduit, each conductor must comply with the requirements of No. 41 (except that tape may be substituted for braid on the separate conductors), and must have a substantial braid covering the whole. For unlined conduit each conductor must comply with requirements of No. 41 (except that tape may be substituted for braid), and in addition must have a braid covering the whole, at least 1/32 of an inch in thickness and sufficiently tenacious to withstand the abrasion of being hauled through the metal conduit.

c. For concentric wire, the inner conductor must comply with the requirements of No. 41 (except that tape may be substituted for braid), and there must be outside of the outer conductor the same insulation as on the inner, the whole to be covered with a substantial braid, which, for unlined conduits, must be at least 1/32 of an inch in thickness, and sufficiently tenacious to withstand the abrasion of being hauled through the metal conduit.

The braid or tape required around each conductor in duplex, twin and concentric cables is to hold the rubber insulation in place and prevent jamming and flattening. All the braids specified in this rule must be properly saturated with a preservative compound.

48. **Armored Cable.**—(For installation rules, see No. 24 A.) a. The armor of such cables must have at least as great strength to resist penetration of nails, etc., as is required for metal conduits (see No. 49 b), and its thickness must not be less than that specified in the following table:—

Nominal Internal Diameter. Inches.	Actual Internal Diameter. Inches.	Actual External Diameter. Inches.	Thickness of Wall. Inches.
1/4	.27	.40	.06
3/8	.36	.54	.08
1/2	.49	.67	.09
3/4	.62	.84	.10

Nominal Internal Diameter. Inches.	Actual Internal Diameter. Inches.	Actual External Diameter. Inches.	Thickness of Wall. Inches.
$\frac{3}{4}$	.82	1.05	.11
1	1.04	1.31	.13
$1\frac{1}{4}$	1.38	1.66	.14
$1\frac{1}{2}$	1.61	1.90	.14
2	2.06	2.37	.15
$2\frac{1}{2}$	2.46	2.87	.20
3	3.06	3.50	.21
$3\frac{1}{2}$	3.54	4.00	.22
4	4.02	4.50	.23
$4\frac{1}{2}$	4.50	5.00	.24
5	5.04	5.56	.25
6	6.06	6.62	.28

An allowance of .02 of an inch for variation in manufacturing and loss of thickness by cleaning will be permitted.

b. The conductors in same, single wire or twin conductors, must have an insulating covering as required by No. 41; if any filler is used to secure a round exterior, it must be impregnated with a moisture repellent, and the whole bunch of conductors and fillers must have a separate exterior covering.

49. Interior Conduits.—(For installation rules, see Nos. 24 n to p and 25.) a. Each length of conduit, whether lined or unlined, must have the maker's name or initials stamped in the metal or attached thereto in a satisfactory manner, so that inspectors can readily see the same.

The use of paper stickers or tags cannot be considered satisfactory methods of marking, as they are readily loosened and lost off in the ordinary handling of the conduit.

Metal Conduits with Lining of Insulating Material.—b. The metal covering or pipe must be at least as strong as the ordinary commercial forms of gas pipe of the same size, and its thickness must be not less than that of standard gas pipe as specified in the table given in No. 48.

c. Must not be seriously affected externally by burning out a wire inside the tube when the iron pipe is connected to one side of the circuit.

d. Must have the insulating lining firmly secured to the pipe.

e. The insulating lining must not crack or break when a length of the conduit is uniformly bent at temperature of 212° Fahrenheit (100° Centigrade), to an angle of ninety degrees, with a curve having a radius of 15 ins., for pipes of one inch and less, and fifteen times the diameter of pipe for larger sizes.

f. The insulating lining must not soften injuriously at any temperature below 212° Fahrenheit (100° Centigrade), and must leave water in which it is boiled practically neutral.

g. The insulating lining must be at least $\frac{1}{32}$ of an inch in thickness. The materials of which it is composed must be of such a nature as will not have a deteriorating effect on the insulation of the conductor, and be sufficiently tough and tenacious to withstand the abrasion test of drawing long lengths of conductors in and out of same.

h. The insulating lining must not be mechanically weak after three days' immersion in water, and when removed from the pipe entire, must not absorb more than ten per cent of its weight of water during 100 hours of submersion.

i. All elbows or bends must be so made that the conduit or lining of same will not be injured. The radius of the curve of the inner edge of any elbow must not be less than $3\frac{1}{2}$ inches.

Unlined Metal Conduits.—j. Pipe sizes to run as follows:—

Trade Size. Inches.	Approximate Internal Diameter. Inches.	Minimum Thickness of Wall. Inches.
$\frac{1}{2}$	.62	.100
$\frac{3}{4}$	.82	.105
1	1.04	.125
$1\frac{1}{4}$	1.38	.135

Trade Size. Inches.	Approximate Internal Diameter. Inches.	Minimum Thickness of Wall. Inches.
1½	1.61	.140
2	2.06	.150
2½	2.46	.200
3	3.06	.210
3½	3.54	.220

At no point (except at screw thread) shall the thickness of wall of finished conduit be less than the minimum specified in last column of above table.

k. Pipe to be thoroughly cleaned to remove all scale. Pipe should be of sufficiently true circular section to admit of cutting true, clean threads, and should be very closely the same in wall thickness at all points with clean square weld.

l. Cleaned pipe to be protected against effects of oxidation, by baked enamel, zinc or other approved coating which will not soften at ordinary temperatures, and of sufficient weight and toughness to successfully withstand rough usage likely to be received during shipment and installation; and of sufficient elasticity to prevent flaking when ½-inch conduit is bent in a curve the inner edge of which has a radius of 3½ inches.

m. All elbows or bends must be so made that the conduit will not be injured. The radius of the curve of the inner edge of any elbow not to be less than 3½ inches.

49 A. Switch and Outlet Boxes.—a. Must be of pressed steel having a wall thickness not less than .081 inch (No. 12 B. & S. gage), or of cast metal having a wall thickness not less than .128 inch (No. 8 B. & S. gage.)

b. Must be well galvanized, enameled or otherwise properly coated, inside and out, to prevent oxidation.

c. Must be so made that all openings not in use will be effectively closed by metal which will afford protection substantially equivalent to the walls of the box.

d. Must be plainly marked, where it may readily be seen when installed, with the name or trade-mark of the manufacturer.

e. Must be arranged to secure in position the conduit or flexible tubing protecting the wire.

This rule will be complied with if the conduit or tubing is firmly secured in position by means of some approved device which may or may not be a part of the box.

f. Boxes used with lined conduit must comply with the foregoing requirements, and in addition must have a tough and tenacious insulating lining at least 1/32 inch thick, firmly secured in position.

g. Switch and outlet boxes must be so arranged that they can be securely fastened in place independently of the support afforded by the conduit piping, except that when entirely exposed, approved boxes, which are headed so as to be firmly supported by screwing on to the conduit pipe, may be used.

h. Switch boxes must completely enclose the switch on sides and back, and must provide a thoroughly substantial support for it. The remaining screws for the box must not be used to secure the switch in position.

i. Covers for outlet boxes must be of metal equal in thickness to that specified for the walls of the box, or must be of metal lined with an insulating material not less than 1/32 inch in thickness, firmly and permanently secured to the metal.

50. Mouldings.—(For wiring rules, see No. 24 k to m.)

Wooden Mouldings.—a. Must have, both outside and inside, at least two coats of waterproof material, or be impregnated with a moisture repellent.

b. Must be made in two pieces, a backing and a capping, and must afford suitable protection from abrasion. Must be so constructed as to thoroughly encase the wire, be provided with a tongue not less than ½ inch in thickness between the conductors, and have exterior walls which, under grooves,

shall not be less than $\frac{3}{8}$ inch in thickness, and on the sides not less than $\frac{1}{4}$ inch in thickness.

It is recommended that only hard-wood moulding be used.

Metal Mouldings.—(For wiring rules, see Nos. 24, k to m, and 25 A.)

c. Each length of such moulding must have maker's name or trade-mark stamped in the metal, or in some manner permanently attached thereto, in order that it may be readily identified in the field.

The use of paper stickers or tags cannot be considered satisfactory methods of marking, as they are readily loosened and lost off in ordinary handling of the moulding.

d. Must be constructed of iron or steel with backing at least .050 inch in thickness, and with capping not less than .040 inch in thickness, and so constructed that when in place the raceway will be entirely closed; must be thoroughly galvanized or coated with an approved rust preventative both inside and out to prevent oxidation.

e. Elbows, couplings and all other similar fittings must be constructed of at least the same thickness and quality of metal as the moulding itself, and so designed that they will both electrically and mechanically secure the different sections together and maintain the continuity of the raceway. The interior surfaces must be free from burrs or sharp corners which might cause abrasion of the wire coverings.

f. Must at all outlets be so arranged that the conductors cannot come in contact with the edges of the metal, either of capping or backing. Specially designed fittings which will interpose substantial barriers between conductors and the edges of metal are recommended.

g. When backing is secured in position by screws or bolts from the inside of the raceway, depressions must be provided to render the heads of the fastenings flush with the moulding.

h. Metal mouldings must be used for exposed work only and must be so constructed as to form an open raceway to be closed by the capping or cover after the wires are laid in.

50 A. Tubes and Bushings.—a. *Construction.*—Must be made straight and free from checks or rough projections, with ends smooth and rounded to facilitate the drawing in of the wire and prevent abrasion of its covering.

b. *Material and Test.*—Must be made of non-combustible insulating material, which, when broken and submerged for 100 hours in pure water at 70° Fahrenheit (21° Centigrade), will not absorb over one-half of one per cent of its weight.

c. *Marking.*—Must have the name, initials or trade-mark of the manufacturer stamped in the ware.

d. *Sizes.*—Dimensions of walls and heads must be at least as great as those given in the following table:—

Diameter of Hole. Inches.	External Diameter. Inches.	Thickness of Wall. Inches.	External Diameter of Head. Inches.	Length of Head. Inches.
$\frac{1}{8}$	$\frac{1}{4}$	$\frac{1}{8}$	$\frac{1}{4}$	$\frac{1}{4}$

	$31\frac{3}{8}$	$\frac{1}{8}$	3	

b. *Supports*.—Bearing points on the surface must be made by ridges or rings about the holes for supporting screws, in order to avoid cracking and breaking when screwed tight.

c. *Material and Test*.—Must be made of non-combustible insulating material, which, when broken and submerged for 100 hours in pure water at 70° Fahrenheit (21° Centigrade), will not absorb over one-half of one per cent of its weight.

d. *Marking*.—Must have the name, initials or trade-mark of the manufacturer stamped in the ware.

e. *Sizes*.—Must conform to the spacings given in the following table:—

Voltage.	Distance from Wire to Surface.	Distance Between Wires.
0-300	$\frac{1}{2}$ inch.	$2\frac{1}{2}$ inches.

This rule will not be interpreted to forbid the placing of the neutral of an Edison three-wire system in the center of a three-wire cleat where the difference of potential between the outside wires is not over 300 volts, provided the outside wires are separated $2\frac{1}{2}$ inches.

50 C. Flexible Tubing.—a. Must have a sufficiently smooth interior surface to allow the ready introduction of the wire.

b. Must be constructed of or treated with materials which will serve as moisture repellents.

c. The tube must be so designed that it will withstand all the abrasion likely to be met with in practice.

d. The linings, if any, must not be removable in lengths of over 3 feet.

e. The $\frac{1}{2}$ -inch tube must be so flexible that it will not crack or break when bent in a circle with 6-inch radius at 50° Fahrenheit (10° Centigrade), and the covering must be thoroughly saturated with a dense moisture-proof compound which will not slide at 150° Fahrenheit (65° Centigrade). Other sizes must be as well made.

f. Must not convey fire on the application of a flame from Bunsen burner to the exterior of the tube when held in a vertical position.

g. Must be sufficiently tough and tenacious to withstand severe tension without injury; the interior diameter must not be diminished or the tube opened up at any point by the application of a reasonable stretching force.

h. Must not close to prevent the insertion of the wire after the tube has been kinked or flattened and straightened out.

51. Switches.—(For installation rules, see Nos. 17 and 22.)

GENERAL RULES.

a. Must, when used for service switches, indicate, on inspection, whether the current be "on" or "off."

b. Must, for constant-current systems, close the main circuit and disconnect the branch wires when turned "off;" must be so constructed that they shall be automatic in action, not stopping between points when started, and must prevent an arc between the points under all circumstances. They must indicate whether the current be "on" or "off."

KNIFE SWITCHES.

Knife switches must be made to comply with the following specifications, except in those few cases where peculiar design allows the switch to fulfil the general requirements in some other way, and where it can successfully withstand the test of Section 4. In such cases the switch should be submitted for special examination before being used.

c. *Base*.—Must be mounted on non-combustible, non-absorptive insulating bases, such as slate or porcelain. Bases with an area of over 25 square inches must have at least four supporting screws. Holes for the supporting screws must be so located or countersunk that there will be at least $\frac{1}{2}$ an inch space, measured over the surface, between the head of the screw or washer and the nearest live metal part, and in all cases when between parts of opposite polarity must be countersunk.

d. *Mounting*.—Pieces carrying the contact jaws and hinge clips must be secured to the base by at least two screws, or else made with a square shoulder, or provided with dowel pins, to prevent possible turnings, and

the nuts or screw-heads on the under side of the base must be countersunk not less than $\frac{1}{4}$ inch and covered with a waterproof compound which will not melt below 150° Fahrenheit (65° Centigrade).

e. Hinges.—Hinges of knife switches must not be used to carry current unless they are equipped with spring washers, held by lock-nuts or pins, or their equivalent, so arranged that a firm and secure connection will be maintained at all positions of the switch blades.

Spring washers must be of sufficient strength to take up any wear in the hinge and maintain a good contact at all times.

f. Metal.—All switches must have ample metal for stiffness and to prevent rise in temperature of any part of over 50° Fahrenheit (28° Centigrade), at full load, the contacts being arranged so that a thoroughly good bearing at every point is obtained with contact surfaces advised for pure copper blades of about one square inch for each 75 amperes; the whole device must be mechanically well made throughout.

g. Cross-Bars.—All cross-bars less than 3 inches in length must be made of insulating material. Bars of 3 inches or over, which are made of metal to insure greater mechanical strength, must be sufficiently separated from the jaws of the switch to prevent arcs following from the contacts to the bar on the opening of the switch under any circumstances. Metal bars should preferably be covered with insulating material.

To prevent possible turning or twisting the cross-bar must be secured to each blade by two screws, or the joints made with square shoulders or provided with dowel-pins.

h. Connections.—Switches for currents of over 30 amperes must be equipped with lugs, firmly screwed or bolted to the switch, and into which the conducting wires shall be soldered. For the smaller sized switches simple clamps can be employed, provided they are heavy enough to stand considerable hard usage.

Where lugs are not provided, a rugged double-V groove clamp is advised. A set-screw gives a contact at only one point, is more likely to become loosened, and is almost sure to cut into the wire. For the smaller sizes, a screw and washer connection with up-turned lugs on the switch terminal gives a satisfactory contact.

i. Test.—Must operate successfully at 50 per cent overload in amperes and 25 per cent excess voltage, under the most severe conditions with which they are liable to meet in practice.

This test is designed to give a reasonable margin between the ordinary rating of the switch and the breaking-down point, thus securing a switch which can always safely handle its normal load. Moreover, there is enough leeway so that a moderate amount of overloading would not injure the switch.

j. Marking.—Must be plainly marked where it will be visible, when the switch is installed, with the name of the maker and the current and the voltage for which the switch is designed.

Switches designed for use on Edison three-wire systems must be marked with both voltages, that is, the voltage between the outside wires and the neutral, and also that between the outside wires, followed by the ampere rating and the words "three-wire." (For example, "125-250 v. 30 a., three-wire.")

k. Spacings.—Spacings must be at least as great as those given in the following table. The spacings specified are correct for switches to be used on direct-current systems, and can therefore be safely followed in devices designed for alternating currents.

125 VOLTS OR LESS:	Minimum Separation of Nearest Metal Parts of Opposite Polarity.	Minimum Break- Distance.
<i>For Switchboards and Panel Boards:</i>		
10 amperes or less.....	$\frac{3}{4}$ inch - - -	$\frac{1}{2}$ inch.
11-30 amperes.....	1 " - - -	$\frac{3}{4}$ "
31-50 ".....	1 $\frac{1}{4}$ " - - -	1 "
<i>For Individual Switches:</i>		
10 amperes or less.....	1 inch - - -	$\frac{3}{4}$ inch.
11-30 amperes.....	1 $\frac{1}{4}$ " - - -	1 "
31-100 ".....	1 $\frac{1}{2}$ " - - -	1 $\frac{1}{4}$ "
101-300 ".....	2 $\frac{1}{4}$ " - - -	2 "
301-600 ".....	2 $\frac{3}{4}$ " - - -	2 $\frac{1}{2}$ "
601-1000 ".....	3 " - - -	3 "

126 TO 250 VOLTS:

For all Switches:

	Min. Sep.	Min. B.-D.
10 amperes or less.....	1½ inch - - -	1½ inch.
11-30 amperes.....	1¾ " - - -	1¾ "
31-100 "	2¼ " - - -	2 "
101-300 "	2½ " - - -	2¼ "
301-600 "	2¾ " - - -	2½ "
601-1000 "	3 " - - -	2¾ "

For 100 ampere switches and larger, the above spacings for 250 volts direct current are also approved for 500 volts alternating current. Switches with these spacings intended for use on alternating-current systems with voltage above 250 volts must be stamped "250-volt D. C.," followed by the alternating-current voltage for which they are designed, and the letters "A. C."

251 TO 600 VOLTS:

For all Switches:

10 amperes or less.....	3½ inch - - -	3 inch.
11-35 amperes.....	4 " - - -	3½ "
36-100 "	4½ " - - -	4 "

Auxiliary breaks or the equivalent are recommended for switches designed for over 300 volts and less than 100 amperes, and will be required on switches designed for use in breaking currents greater than 100 amperes at a pressure of more than 300 volts.

For three-wire Edison systems the separations and break distances for plain three-pole knife switches must not be less than those required in the above table for switches designed for the voltage between the neutral and outside wires.

SNAP SWITCHES.

Flush, push-button, door, fixture and other snap switches used on constant-potential systems, must be constructed in accordance with the following specifications.

l. Base.—Current-carrying parts must be mounted on non-combustible, non-absorptive, insulating bases, such as slate or porcelain, and the holes for supporting screws should be countersunk not less than $\frac{1}{4}$ of an inch. There must in no case be less than $\frac{3}{64}$ of an inch space between supporting screws and current-carrying parts.

Sub-bases of non-combustible, non-absorptive insulating material, which will separate the wires at least $\frac{1}{4}$ inch from the surface wired over, must be furnished with all snap switches used in exposed or moulding work.

m. Mounting.—Pieces carrying contact jaws must be secured to the base by at least two screws, or else made with a square shoulder, or provided with dowel-pins or otherwise arranged to prevent possible turnings; and the nuts or screw-heads on the under side of the base must be countersunk not less than $\frac{1}{4}$ inch, and covered with a waterproof compound which will not melt below 150° Fahrenheit (65° Centigrade).

n. Metal.—All switches must have ample metal for stiffness and to prevent rise in temperature of any part of over 50° Fahrenheit (28° Centigrade) at full load, the contacts being arranged so that a thoroughly good bearing at every point is obtained. The whole device must be mechanically well made throughout.

In order to meet the above requirements on temperature rise without causing excessive friction and wear on current-carrying parts, contact surfaces of from 0.1 to 0.15 square inch for each 10 amperes will be required, depending upon the metal used and the form of construction adopted.

o. Insulating Material.—Any material used for insulating current-carrying parts must retain its insulating and mechanical strength when subject to continued use, and must not soften at a temperature of 212° Fahrenheit (100° Centigrade). It must also be non-absorptive.

p. Binding Posts.—Binding posts must be substantially made, and the screws must be of such size that the threads will not strip when set up tight.

A set-screw is likely to become loosened and is almost sure to cut into the wire. A binding screw under the head of which the wire may be clamped and a terminal plate provided with upturned lugs or some other equivalent arrangement, afford reliable contact. After July 1, 1908, switches with the set-screw form of contact will not be approved.

q. Covers.—Covers made of conducting material, except face plates for flush switches, must be lined on sides and top with insulating, tough and tenacious material at least $\frac{1}{32}$ inch in thickness, firmly secured so that it

will not fall out with ordinary handling. The side lining must extend slightly beyond the lower edge of the cover.

r. Handle or Button.—The handle or button or any exposed parts must not be in electrical connection with the circuit.

s. Test.—Must "make" and "break" with a quick snap, and must not stop when motion has once been imparted by the button or handle.

Must operate successfully at 50 per cent overload in amperes and at 125 volt direct current, for all 125 volt or less switches, and at 250 volt direct current, for all 125 to 250 volt switches under the most severe conditions which they are liable to meet in practice.

When slowly turned "on" and "off" at the rate of about two or three times per minute, while carrying the rated current at rated voltage, must "make" and "break" the circuit 6,000 times before failing.

t. Marking.—Must be plainly marked, where it may be readily seen after the device is installed, with the name or trade-mark of the maker and the current and voltage for which the switch is designed.

On flush switches these markings may be placed on the back of the face plate or on the sub-plate. On other types they must be placed on the front of the cap, cover or plate.

Switches which indicate whether the current is "on" or "off" are recommended.

52. Cut-Outs and Circuit Breakers.—(For installation rules, see Nos. 17 and 21.) *These requirements do not apply to rosettes, attachment plugs, car lighting cut-outs and protective devices for signaling systems.*

GENERAL RULES.

a. Must be supported on bases of non-combustible, non-absorptive insulating material.

b. Cut-outs must be of plug or cartridge type, when not arranged in approved cabinets, so as to obviate any danger of the melted fuse metal coming in contact with any substance which might be ignited thereby.

c. Cut-outs must operate successfully on short-circuits, under the most severe conditions with which they are liable to meet in practice, at 25 per cent above their rated voltage, and for link fuse cut-outs with fuses rated at 50 per cent above the current for which the cut-out is designed, and for enclosed fuse cut-outs with the largest fuses for which the cut-out is designed.

With link fuse cut-outs there is always the possibility of a larger fuse being put into the cut-out than it was designed for, which is not true of enclosed fuse cut-outs classified as required under No. 52q. Again, the voltage in most plants can, under some conditions, rise considerably above the normal. The need of some margin as a factor of safety to prevent the cut-outs from being ruined in ordinary service, is therefore evident.

The most severe service which can be required of a cut-out in practice is to open a "dead short-circuit" with only one fuse blowing, and it is with these conditions that all tests should be made. (See Section j.)

d. Circuit-breakers must operate successfully on short-circuits under the most severe conditions with which they are liable to meet in practice, at 25 per cent above their rated voltage and with the circuit-breaker set at the highest possible opening point.

For the same reason as in Section c.

e. Must be plainly marked where it will always be visible, with the name of the maker, and current and voltage for which the device is designed.

LINK-FUSE CUT-OUTS.

(Cut-outs of porcelain are not approved for link fuses.)

The following rules are intended to cover open link fuses mounted on slate or marble bases, including switchboards, tablet-boards and single fuse-blocks. They do not apply to fuses mounted on porcelain bases, to the ordinary porcelain cut-out blocks, enclosed fuses, or any special or covered type of fuse. When tablet-boards or single fuse-blocks with such open link fuses on them are used in general wiring, they must be enclosed in cabinet boxes made to meet the requirements of No. 51. This is necessary, because a severe flash may occur when such fuses melt, so that they would be dangerous if exposed in the neighborhood of any combustible material.

f. Base. Must be mounted on slate or marble bases. Bases with an area of over 25 square inches must have at least four supporting screws. Holes for supporting screws must be kept outside of the area included by

the outside edges of the fuse-block terminals, and must be so located or countersunk that there will be at least $\frac{1}{2}$ inch space, measured over the surface, between the head of the screw or washer and the nearest live part.

g. Mounting.—Nuts or screw heads on the under side of the base must be countersunk not less than $\frac{1}{4}$ inch, and covered with a waterproof compound which will not melt below 150° Fahrenheit (65° Centigrade).

h. Metal.—All fuse-block terminals must have ample metal for stiffness and to prevent rise in temperature of any part over 50° Fahrenheit (28° Centigrade) at full load. Terminals, as far as practicable, should be made of compact form instead of being rolled out in thin strips; and sharp edges or thin projecting pieces, as on wing thumb nuts and the like, should be avoided. Thin metal, sharp edges and projecting pieces are much more likely to cause an arc to start than a more solid mass of metal. It is a good plan to round all corners of the terminals and to chamfer the edges.

i. Connections.—Clamps for connecting the wires to the fuse-block terminals must be of solid, rugged construction, so as to insure a thoroughly good connection and to withstand considerable hard usage. For fuses rated at over 30 amperes, lugs firmly screwed or bolted to the terminals and into which the conducting wires are soldered must be used.

See note under No. 51 h.

j. Test.—Must operate successfully when blowing only one fuse at a time on short circuits with fuses rated at 50 per cent above and with a voltage 25 per cent above the current and voltage for which the cut-out is designed.

k. Marking.—Must be plainly marked, where it will be visible when the cut-out block is installed, with the name of the maker and the current and the voltage for which the block is designed.

l. Spacings.—Spacings must be at least as great as those given in the following table, which applies only to plain, open link-fuses mounted on slate or marble bases. The spaces given are correct for fuse-blocks to be used on direct-current systems, and can therefore be safely followed in devices designed for alternating currents. If the copper fuse-tips overhang the edges of the fuse-block terminals, the spacings should be measured between the nearest edges of the tips.

	Minimum Separation of Nearest Metal Parts of Opposite Polarity.	Minimum Break Distance.
125 VOLTS OR LESS:		
10 amperes or less.....	$\frac{3}{4}$ inch - -	$\frac{3}{4}$ inch.
11-100 amperes.....	1 " - -	$\frac{1}{2}$ "
101-300 ".....	1 " - -	1 " "
301-1000 ".....	1 $\frac{1}{4}$ " - -	1 $\frac{1}{4}$ "
126 TO 250 VOLTS:		
10 amperes or less.....	1 $\frac{1}{2}$ inch - -	1 $\frac{1}{2}$ inch.
11-100 amperes.....	1 $\frac{3}{4}$ " - -	1 $\frac{1}{4}$ "
101-300 ".....	2 " - -	1 $\frac{1}{2}$ "
301-1000 ".....	2 $\frac{1}{2}$ " - -	2 "

A space must be maintained between fuse terminals of the same polarity of at least $\frac{1}{2}$ inch for voltages up to 125, and of at least $\frac{3}{4}$ inch for voltages from 126 to 250. This is the minimum distance allowable, and greater separation should be provided when practicable.

For 250 volt boards or blocks with the ordinary front-connected terminals, except where these have a mass of compact form, equivalent to the back-connected terminals usually found in switchboard work, a substantial barrier of insulating material, not less than $\frac{1}{4}$ of an inch in thickness, must be placed in the "break" gap—this barrier to extend out from the base at least $\frac{1}{4}$ of an inch farther than any bare live part of the fuse-block terminal, including binding screws, nuts and the like.

For three-wire systems cut-outs must have the break-distance required for circuits of the potential of the outside wires.

ENCLOSED-FUSE CUT-OUTS—PLUG AND CARTRIDGE TYPE.

m. Base.—Must be made of non-combustible, non-absorptive, insulating material. Blocks with an area of over 25 square inches must have at least four supporting screws. Holes for supporting screws must be so located or countersunk that there will be at least $\frac{1}{2}$ inch space, measured over the surface, between the screw-head or washer and the nearest live metal part, and in all cases when between parts of opposite polarity must be countersunk.

n. Mounting.—Nuts or screw-heads on the under side of the base must be countersunk at least $\frac{1}{4}$ of an inch and covered with a waterproof compound which will not melt below 150° Fahrenheit (65° Centigrade).

o. Terminals.—Terminals must be of either the Edison plug, spring clip or knife-blade type, of approved design, to take the corresponding standard enclosed fuses. They must be secured to the base by two screws or the equivalent, so as to prevent them from turning, and must be so made as to secure a thoroughly good contact with the fuse. End stops must be provided to insure the proper location of the cartridge fuse in the cut-out.

p. Connections.—Clamps for connecting wires to the terminals must be of a design which will insure a thoroughly good connection, and must be sufficiently strong and heavy to withstand considerable hard usage. For fuses rated to carry over thirty amperes, lugs firmly screwed or bolted to the terminals and into which the connecting wires shall be soldered must be used.

q. Classification.—Must be classified as regards both current and voltage as given in the following table, and must be so designed that the bases of one class cannot be used with fuses of another class rated for a higher current or voltage.

0-250 VOLTS:

0- 30 amperes.
31- 60 "
61-100 "
101-200 "
201-400 "
401-600 "

251-600 VOLTS:

0- 30 amperes.
31- 60 "
61-100 "
101-200 "
201-400 "

r. Design.—Must be of such a design that it will not be easy to form accidental short circuit across live metal parts of opposite polarity on the block or on the fuses in the block.

s. Marking.—Must be marked, where it will be plainly visible when the block is installed, with the name of the maker and the voltage and range of current for which it is designed.

53. Fuses.—(For installation rules, see Nos. 17 and 21.)

LINK FUSES.

a. Terminals.—Must have contact surfaces or tips of harder metal, having perfect electrical connections with the fusible part of the strip.

The use of the hard metal tip is to afford a strong mechanical bearing for the screws, clamps or other devices provided for holding the fuse.

b. Rating.—Must be stamped with about 80 per cent of the maximum current which they can carry indefinitely, thus allowing about 25 per cent overload before the fuse melts.

With naked open fuses, or ordinary shapes and with not over 500 amperes capacity, the minimum current which will melt them in about five minutes may be safely taken as the melting point, as the fuse practically reaches its maximum temperature in this time. With larger fuses a longer time is necessary. This data is given to facilitate testing.

c. Marking.—Fuse terminals must be stamped with the maker's name or initials, or with some known trade-mark.

ENCLOSED FUSES—PLUG AND CARTRIDGE TYPE.

These requirements do not apply to fuses for rosettes, attachment plugs, car lighting cut-outs and protective devices for signaling systems.

d. Construction.—The fuse plug or cartridge must be sufficiently dust-tight so that lint and dust cannot collect around the fusible wire and become ignited when the fuse is blown.

The fusible wire must be attached to the plug or cartridge terminals in such a way as to secure a thoroughly good connection and to make it difficult for it to be replaced when melted.

e. Classification.—Must be classified to correspond with the different classes of cut-out blocks, and must be so designed that it will be impossible to put any fuse of a given class into a cut-out block which is designed for a current or voltage lower than that of the class to which the fuse belongs.

f. Terminal.—The fuse terminals must be sufficiently heavy to insure mechanical strength and rigidity. The styles of terminals must be as follows:

0-250 VOLTS:

0-30 Amps.	{ A { Cartridge fuse } to { a, spring clip terminals. (ferrule contact) } fit { b, Edison plug casings. B Approved plugs for Edison cut-outs.
31-60 "	{ Cartridge fuse } to { a, spring clip terminals. (ferrule contact) } fit { b, Edison plug casings.
61-100 "	{ Cartridge fuse (knife-blade contact).
101-200 "	
201-400 "	
401-600 "	

251-600 VOLTS:

0-30 Amps.	{ Cartridge fuse (ferrule contact).
31-60 "	
61-100 "	{ Cartridge fuse (knife-blade contact).
101-200 "	
201-400 "	
401-600 "	

g. Dimensions.—Cartridge enclosed fuses and corresponding cut-out blocks must conform to the dimensions given in the Table, on next page.

h. Rating.—Fuses must be so constructed that with the surrounding atmosphere at a temperature of 75° Fahrenheit (24° Centigrade) they will carry indefinitely a current 10 per cent greater than that at which they are rated, and at a current 25 per cent greater than the rating, they will open the circuit without reaching a temperature which will injure the fuse tube or terminals of the fuse block. With a current 50 per cent greater than the rating and at room temperature of 75° Fahrenheit (24° Centigrade), the fuses starting cold, must blow within the time specified below:—

0- 30 amperes,	30 seconds.
31- 60 "	1 minute.
61-100 "	2 minutes.
101-200 "	4 "
201-400 "	8 "
401-600 "	10 "

i. Marking.—Must be marked, where it will be plainly visible, with the name or trade-mark of the maker, the voltage and current for which the fuse is designed, and the words "National Electrical Code Standard." Each fuse must have a label, the color of which must be green for 250-volt fuses and red for 600-volt fuses.

It will be satisfactory to abbreviate the above designation to "N. E. Code St'd" where space is necessarily limited.

j. Temperature Rise.—The temperature of the exterior of the fuse enclosure must not rise more than 125° Fahrenheit (70° Centigrade) above that of the surrounding air when the fuse is carrying the current for which it is rated.

k. Test.—Must not hold an arc or throw out melted metal or sufficient flame to ignite easily inflammable material on or near the cut-out when only one fuse is blown at a time on a short circuit on a system of the voltage for which the fuse is rated.

The normal capacity of the system must be in excess of the load on it just previous to the test by at least five times the rated capacity or the fuse under test.

The resistance of the circuit up to the cut-out terminals must be such that the impressed voltage at the terminals will be decreased not more than one per cent, when a current of 100 amperes is passed between them.

For convenience a current of different value may be used, in which case the per cent drop in voltage allowable would vary in direct proportion to the difference in current used.

The above requirement regarding the capacity of the testing circuit is to guard against making the test on a system of so small a capacity that the conditions would be sufficiently favorable to allow really poor fuses to stand the test acceptably. On the other hand, it must be remembered that if the test is made on a system of very large capacity, and especially if there is but little resistance between the generators and fuse, the conditions may be more severe than are liable to be met with in practice outside of the large power stations, the result being that fuses entirely safe for general use may be rejected if such test is insisted upon.

TABLE OF DIMENSIONS OF THE NATIONAL ELECTRIC
CODE STANDARD CARTRIDGE ENCLOSED FUSE.

Form 1.—
Cartridge
Fuse (Ferrule
Contact).
Form 2.—
Cartridge
Fuse (Knife-
blade Con-
tact).

Voltage.	Rated Capacity. Amperes.	A Length Over Terminals. Inches.	B Distance Between Contact Clips. Inches.	C Width of Contact Clips. Inches.	D Diameter of Ferrules or Thickness of Terminal Blades. Inches.	E Min. Length of Ferrules or of Terminal Outside of Tube. Inches.	F Diameter of Tube. Inches.	G Width of Terminal Blades. Inches.	Rated Capacity. Amperes.
0-250	0-30	2	1	$\frac{1}{2}$	$\frac{1}{8}$	$\frac{1}{2}$	$\frac{1}{2}$	Form 1	0-30
	31-60	3	$1\frac{1}{4}$	$\frac{5}{8}$	$\frac{1}{8}$	$\frac{5}{8}$	$\frac{5}{8}$	Form 1	31-60
	61-100	$5\frac{1}{2}$	4	$\frac{7}{8}$	$\frac{1}{4}$	1	1	Form 2	61-100
	101-200	$7\frac{1}{2}$	$4\frac{1}{2}$	$1\frac{1}{4}$	$\frac{1}{4}$	$1\frac{1}{2}$	$1\frac{1}{2}$	Form 2	101-200

	101-200	$9\frac{1}{4}$	7	$1\frac{1}{4}$	$\frac{1}{4}$	$1\frac{1}{2}$	$1\frac{1}{4}$	Form 2	101-200
251-600	201-400	$11\frac{1}{2}$	8	$1\frac{5}{8}$	$\frac{1}{4}$	$1\frac{1}{2}$	$2\frac{1}{4}$	Form 2	201-400

53 A. Tablet and Panel Boards.—The following *minimum* distance between bare live metal parts (bus-bars, etc.) must be maintained:—

Between parts of opposite polarity, except at switches and link fuses,		Between parts of same polarity,
When mounted on the same surface.	When held free in the air.	At link fuses.
0-125 volts $\frac{3}{4}$ inch	$\frac{1}{2}$ inch	$\frac{1}{2}$ inch
126-250 volts $1\frac{1}{4}$ "	$\frac{3}{4}$ "	$\frac{3}{4}$ "

At switches or enclosed fuses, parts of the same polarity may be placed as close together as convenience in handling will allow.

It should be noted that the above distances are the *minimum* allowable, and it is urged that greater distances be adopted wherever the conditions will permit.

The spacings given in the first column apply to the branch conductors where inclosed fuses are used. Where link fuses or knife switches are used, the spacings must be at least as great as those required by Nos. 51 and 52.

The spacings given in the second column apply to the distance between the raised main bars, and between these bars and the branch bars over which they pass.

The spacings given in the third column are intended to prevent the melting of a link fuse by the blowing of an adjacent fuse of the same polarity.

54. Cut-Out Cabinets.—*a. Material.*—Cabinets must be substantially constructed of non-combustible, non-absorptive material, or of wood. When wood is used the inside of the cabinet must be completely lined with a non-combustible insulating material. Slate or marble at least $\frac{1}{4}$ inch in thickness is strongly recommended for such lining, but, except with metal conduit systems, asbestos board at least $\frac{1}{4}$ inch in thickness may be used in dry places if firmly secured by shellac and tacks.

With metal conduit systems the lining of either the box or the gutter must be of 1/16 inch galvanized, painted or enameled steel, or preferably $\frac{1}{4}$ inch slate or marble.

The object of the lining of such cut-out cabinets or gutters is to render the same approximately fireproof in case of short circuit after the wires leave the protecting metal conduits.

Two thicknesses of 1-32 inch steel may be used instead of one 1-16 inch.

With wood cabinets the wood should be thoroughly filled and painted before the lining is put into place.

b. Door.—The door must close against a rabbet, so as to be perfectly dust-tight. Strong hinges and a strong hook or catch are required. Glass doors must be glazed with heavy glass, not less than $\frac{1}{4}$ inch in thickness, and panes should not exceed 300 square inches in area. A space of at least two inches must be allowed between the fuses and the door. This is necessary to prevent cracking or breaking by the severe blow and intense heat which may be produced under some conditions.

A cabinet is of little use unless the door is kept tightly closed, and especial attention is therefore called to the importance of having a strong and reliable catch or other fastening. A spring catch is advised if a good one can be obtained, but most of those sold for use on cupboards, etc., are so small that they fail to catch when the door shrinks a little, or are so weak that they soon give out.

It is advised that the bottoms of cabinets be given a decided slant to prevent their use as a shelf, as well as the accumulation of dust, etc.

c. Bushings.—Bushings through which wires enter must fit tightly the holes in the box, and must be of *approved* construction. The wires should completely fill the holes in the bushings, using tape to build up the wire, if necessary, so as to keep out the dust.

54 A. Rosettes.—Ceiling rosettes, both fused and fuseless, must be constructed in accordance with the following specifications:—

a. Base.—Current-carrying parts must be mounted on non-combustible, non-absorptive, insulating bases. There should be no openings through the rosette base except those for the supporting screws and in the concealed type for the conductors also, and these openings should not be made any larger than necessary.

There must be at least $\frac{1}{4}$ inch space, measured over the surface, between supporting screws and current-carrying parts. The supporting screws must be so located or countersunk that the flexible cord cannot come in contact with them.

Bases for the knob and cleat type must have at least two holes for supporting screws; must be high enough to keep the wires and terminals at least $\frac{1}{4}$ inch from the surface to which the rosette is attached, and must have a porcelain lug under each terminal to prevent the rosette from being

placed over projections which would reduce the separation to less than $\frac{1}{8}$ inch.

Bases for the moulding and conduit box types must be high enough to keep the wires and terminals at least $\frac{1}{8}$ inch from the surface wired over.

b. *Mounting*.—Contact pieces and terminals must be secured in position by at least two screws, or made with a square shoulder, or otherwise arranged to prevent turning.

The nuts or screw head on the under side of the base must be countersunk not less than $\frac{1}{8}$ inch and covered with a waterproof compound which will not melt below 150° Fahrenheit (65° Centigrade).

c. *Terminals*.—Line terminal plates must be at least .07 inch in thickness, and terminal screws must not be smaller than No. 6 standard screw with about 32 threads per inch.

Terminal plates for the flexible cord and for fuses must be at least .06 inch in thickness. The connection to these plates shall be by binding screws not smaller than No. 5 standard screw with about 40 threads per inch. At all binding screws for line wires and for flexible cord, up-turned lugs, or some equivalent arrangement, must be provided which will secure the wires being held under the screw heads.

d. *Cord Inlet*.—The diameter of the cord inlet hole should measure $18/32$ inch in order that standard portable cord may be used.

e. *Knot Space*.—Ample space must be provided for a substantial knot tied in the cord as a whole.

All parts of the rosette upon which the knot is likely to bear must be smooth and well rounded.

f. *Cover*.—When the rosette is made in two parts, the cover must be secured to the base so that it will not work loose.

In fused rosettes, the cover must fit closely over the base so as to prevent the accumulation of dust or dirt on the inside, and also to prevent any flash or melted metal from being thrown out when the fuses melt.

g. *Markings*.—Must be plainly marked where it may readily be seen after the rosette has been installed, with the name or trade-mark of the manufacturer, and the rating in amperes and volts. Fuseless rosettes may be rated 3 amperes, 250 volts; fused rosettes, with link fuses, not over 2 amperes, 125 volts.

h. *Test*.—Fused rosettes must have a fuse in each pole and must operate successfully when short-circuited on the voltage for which they are designed, the test being made with the two fuses in circuit.

When link fuses are used the test shall be made with fuse wire which melts at about 7 amperes in one-inch lengths. The larger fuse is specified for the test in order to more nearly approximate the severe conditions obtained when only one 2-ampere fuse (the rating of the rosette) is blown at a time.

Fused rosettes equipped with enclosed fuses are much preferable to the link fuse rosettes.

55. *Sockets*.—(For installation rules, see No. 27.) Sockets of all kinds, including wall receptacles, must be constructed in accordance with the following specifications:—

a. *Standard Sizes*.—The standard lamp socket must be suitable for use on any voltage not exceeding 250 and with any size lamp up to fifty candle-power. For lamps larger than fifty candle-power a standard keyless socket may be used, or if a key is required, a special socket designed for the current to be used must be made. Any special sockets must follow the general spirit of these specifications.

b. *Marking*.—All sockets must be marked with the manufacturer's name or trade-mark. The standard key socket must also be plainly marked 250 v. 50 c. p. Receptacles, keyless sockets and special sockets must be marked with the current and voltage for which they are designed.

c. *Shell*.—Metal used for shells must be moderately hard, but not hard enough to be brittle or so soft as to be easily dented or knocked out of shape. Brass shells must be at least thirteen one-thousandths of an inch in thickness, and shells of any other material must be thick enough to give the same stiffness and strength as the required thickness of brass.

d. *Lining*.—The inside of the shells must be lined with insulating material, which must absolutely prevent the shell from becoming a part of

the circuit, even though the wires inside the sockets should become loosened or detached from their position under the binding screws.

The material used for lining must be at least $1/32$ of an inch in thickness, and must be tough and tenacious. It must not be injuriously affected by the heat from the largest lamp permitted in the socket, and must leave water in which it is boiled practically neutral. It must be so firmly secured to the shell that it will not fall out with ordinary handling of the socket. It is preferable to have the lining in one piece.

The cap must also be lined, and this lining must comply with the requirements for shell linings.

The shell lining should extend beyond the shell far enough so that no part of the lamp base is exposed when a lamp is in the socket. The standard Edison lamp base measures 15-16 inches in a vertical plane from the bottom of the center contact to the upper edge of the screw-shell.

In sockets and receptacles of standard forms a ring of any material inserted between an outer metal shell of the device and the inner screw shell for insulating purposes and separable from the device as a whole, is considered an undesirable form of construction. This does not apply to the use of rings in lamp clusters or in devices where the outer shell is of porcelain, where such rings serve to hold the several porcelain parts together, and are thus a necessary part of the whole structure of the device.

e. Cap.—Caps, when of sheet brass, must be at least thirteen one-thousandths of an inch in thickness, and when cast or made of other metals must be of equivalent strength. The inlet piece, except for special sockets, must be tapped with a standard $\frac{1}{4}$ inch pipe thread. It must contain sufficient metal for a full, strong thread, and when not in one piece with the cap, must be joined to it in such a way as to give the strength of a single piece.

There must be sufficient room in the cap to enable the ordinary wireman to easily and quickly make a knot in the cord and to push it into place in the cap without crowding. All parts of the cap upon which the knot is likely to bear must be smooth and well insulated.

The cap lining called for in the note to Section *d* will provide a sufficiently smooth and well insulated surface for the knot to bear upon.

Sockets with an outlet threaded for $\frac{1}{4}$ -inch pipe will, of course, be approved where circumstances demand their use. The side outlet is necessary with most stiff pendants and for the proper use of reinforced flexible cord, as explained in the note to No. 28 *d*.

f. Frame and Screws.—The frame which holds the moving parts must be sufficiently heavy to give ample strength and stiffness.

Brass pieces containing screw threads must be at least six one-hundredths of an inch in thickness.

Binding post screws must not be smaller than No. 5 standard screw with about 40 threads per inch.

g. Spacing.—Points of opposite polarity must everywhere be kept not less than $3/64$ of an inch apart, unless separated by a reliable insulation.

h. Connections.—The connecting points for the flexible cord must be made to very securely grip a No. 16 or 18 B. & S. gage conductor. An up-turned lug, arranged so that the cord may be gripped between the screw and the lug in such a way that it cannot possibly come out, is strongly advised.

i. Lamp Holder.—The socket must firmly hold the lamp in place so that it cannot be easily jarred out, and must provide a contact good enough to prevent undue heating with the maximum current allowed. The holding pieces, springs and the like, if a part of the circuit, must not be sufficiently exposed to allow them to be brought in contact with anything outside of the lamp and socket.

j. Base.—With the exception of the lining, all parts of insulating material inside the shell must be made of porcelain.

k. Key.—The socket key-handle must be of such a material that it will not soften from the heat of a fifty candle-power lamp hanging downwards from the socket in the air at 70° Fahrenheit (21° Centigrade), and must be securely, but not necessarily rigidly, attached to the metal spindle which it is designed to turn.

l. Sealing.—All screws in porcelain pieces, which can be firmly sealed in place, must be so sealed by a waterproof compound which will not melt below 200° Fahrenheit (93° Centigrade.)

m. Putting Together.—The socket as a whole must be so put together that it will not rattle to pieces. Bayonet joints or an equivalent are recommended.

n. Test.—The socket, when slowly turned "on and off" at the rate of about two or three times per minute, while carrying a load of one ampere at 250 volts, must "make" and "break" the circuit 6,000 times before failing.

o. Keyless Sockets.—Keyless sockets of all kinds must comply with the requirements for key sockets as far as they apply.

p. Sockets of Insulating Material.—Sockets made of porcelain or other insulating material must conform to the above requirements as far as they apply, and all parts must be strong enough to withstand a moderate amount of hard usage without breaking.

Porcelain shell sockets being subject to breakage, and constituting a hazard when broken, will not be accepted for use in places where they would be exposed to hard usage.

q. Inlet Bushing.—When the socket is not attached to a fixture, the threaded inlet must be provided with a strong insulating bushing having a *smooth* hole at least $\frac{9}{32}$ of an inch in diameter. The edges of the bushing must be rounded and all inside fins removed, so that in no place will the cord be subjected to the cutting or wearing action of a sharp edge.

Bushings for sockets having an outlet threaded for $\frac{1}{2}$ -inch pipe should have a hole $\frac{13}{32}$ of an inch in diameter, so that they will accommodate *approved* reinforced flexible cord.

56. Hanger-boards for Series Arc Lamps.—**a.** Hanger-boards must be so constructed that all wires and current-carrying devices thereon will be exposed to view and thoroughly insulated by being mounted on a non-combustible, non-absorptive, insulating substance. All switches attached to the same must be so constructed that they shall be automatic in their action, cutting off both poles to the lamp, not stopping between points when started and preventing an arc between points under all circumstances.

57. Arc Lamps.—(For installation rules, see Nos. 19 and 29.) **a.** Must be provided with reliable stops to prevent carbons from falling out in case the clamps become loose.

b. All exposed parts must be carefully insulated from the circuit.

c. Must, for constant-current systems, be provided with an *approved* hand switch, and an automatic switch that will shunt the current around the carbons, should they fail to feed properly.

The hand switch to be approved, if placed anywhere except on the lamp itself, must comply with requirements for switches on hanger-boards as laid down in No. 56.

58. Spark Arresters.—(For installation rules, see Nos. 19 c and 29 c.)

a. Spark arresters must so close the upper orifice of the globe that it will be impossible for any sparks, thrown off by the carbons, to escape.

59. Insulating Joints.—(See No. 26 a.)—**a.** Must be entirely made of material that will resist the action of illuminating gases, and will not give way or soften under the heat of an ordinary gas flame or leak under a moderate pressure. Must be so arranged that a deposit of moisture will not destroy the insulating effect; must show a dielectric strength between gas-pipe attachments sufficient to resist throughout five minutes the application of an electro-motive force of 4,000 volts; and must be sufficiently strong to resist the strain to which they are liable to be subjected during installation.

Insulating joints having soft rubber in their construction will not be approved.

60. Rheostats.—(For installation rules, see Nos. 4 a and 8 c.)

a. Materials.—Must be made entirely of non-combustible materials, except such minor parts as handles, magnet insulation, etc. All segments, lever arms, etc., must be mounted on non-combustible, non-absorptive, insulating material.

Rheostats used in dusty or linty places or where exposed to flyings of combustible material, must be so constructed that even if the resistive conductor be fused by excessive current, the arc or any attendant flame will be quickly and safely extinguished. Rheostats used in places where the above conditions do not exist may be of any approved type.

b. Construction.—Must be so constructed that when mounted on a plane surface the casing will make contact with such surface only at the

points of support. An air space of at least $\frac{1}{4}$ inch between the rheostat casing and the supporting surface will be required.

The construction throughout must be heavy, rugged and thoroughly workmanlike.

c. Connections.—Clamps for connecting wires to the terminals must be of a design that will insure a thoroughly good connection, and must be sufficiently strong and heavy to withstand considerable hard usage. For currents above fifty amperes, lugs firmly screwed or bolted to the terminals, and into which the connecting wires shall be soldered, must be used.

Clamps or lugs will not be required when leads designed for soldered connections are provided.

d. Marking.—Must be plainly marked, where it may be readily seen after the device is installed, with the rating and the name of the maker; and the terminals of motor-starting rheostats must be marked to indicate to what part of the circuit each is to be connected, as "line," "armature" and "field."

e. Contacts.—The design of the fixed and movable contacts and the resistance in each section must be such as to secure the least tendency toward arcing and roughening of the contacts, even with careless handling or the presence of dirt.

In motor-starting rheostats, the contact at which the circuit is broken by the lever arm when moving from the running to the starting position, must be so designed that there will be no detrimental arcing. The final contact, if any, on which the arm is brought to rest in the starting position must have no electrical connection.

Experience has shown that sharp edges and segments of thin material help to maintain an arc, and it is recommended that these be avoided. Segments of heavy construction have a considerable cooling effect on the air, and rounded corners tend to spread it out and thus dissipate it.

It is recommended that the circuit-breaking contacts be so constructed as to "break" with a quick snap, independently of the slowness of movement of the operator's hand, or that a magnetic blowout or equivalent device be used. For dial type rheostats the movable contact should be flexible in a plane at right angle to the plane of its movement, and for medium and larger sizes the stationary contacts should be readily renewable.

f. No-Voltage Release.—Motor-starting rheostats must be so designed that the contact arm cannot be left on intermediate segments, and must be provided with an automatic device which will interrupt the supply circuit before the speed of the motor falls to less than one third of its normal value.

g. Overload-Release.—Overload-release devices which are inoperative during the process of starting a motor will not be approved unless other circuit-breakers or fuses are installed in connection with them.

If, for instance, the over-release device simply releases the starting arm and allows it to fly back and break the circuit, it is inoperative while the arm is being moved from the starting to the running position.

h. Test.—Must, after 100 operations under the most severe normal conditions for which the device is designed, show no serious burning of the contacts or other faults, and the release mechanism of motor-starting rheostats must not be impaired by such a test.

Field rheostats, or main-line regulators intended for continuous use, must not be burned out or depreciated by carrying the full normal current on any step for an indefinite period. Regulators intended for intermittent use (such as on electric cranes, elevators, etc.) must be able to carry their rated current on any step for as long a time as the character of the apparatus which they control will permit them to be used continuously.

61. Reactive Coils and Condensers.—**a.** Reactive coils must be made of non-combustible material, mounted on non-combustible bases and treated, in general, as sources of heat.

b. Condensers must be treated like other apparatus operating with equivalent voltage and currents. They must have non-combustible cases and supports, and must be isolated from all combustible material and, in general, treated as sources of heat.

62. Transformers.—(For installation rules, see Nos. 11, 13, 13A and 36.)

a. Must not be placed in any but metallic or other non-combustible cases.

On account of the possible dangers from burn-outs in the coils. (See note under No. 11 a.)

It is advised that every transformer be so designed and connected that the middle point of the secondary coil can be reached if, at any future time, it should be desired to ground it.

b. Must be constructed to comply with the following tests:—

1. Shall be run for eight consecutive hours at full load in watts under conditions of service, and at the end of that time the rise in temperature, as measured by the increase of resistance of the primary and secondary coils, shall not exceed 175° Fahrenheit (97° Centigrade).
2. The insulation of transformers when heated shall withstand continuously for five minutes a difference of potential of 10,000 volts (alternating) between primary and secondary coils and between the primary coils and core, and a no-load "run" at double voltage for thirty minutes.

63. **Lightning Arresters.**—(For installation rules, see No. 5.) a. Lightning arresters must be of *approved* construction. (See list of Electrical Fittings.)

Class E.—MISCELLANEOUS.

64. **Signaling Systems.**—*Governing wiring for telephone, telegraph, district messenger and call-bell circuits, fire and burglar alarms, and all similar systems which are hazardous only because of their liability to become crossed with electric light, heat or power circuits.*

a. Outside wires should be run in underground ducts or strung on poles, and, kept off the roofs of buildings, except by special permission of the Inspection Department having jurisdiction, and must not be placed on the same cross-arm with electric light or power wires. They should not occupy the same duct, manhole or handhole of conduit systems with electric light or power wires.

Single manholes, or handholes, may be separated into sections by means of partitions of brick or tile so as to be considered as conforming with the above rule.

The liability of accidental crossing of overhead signaling circuits with electric light and power circuits may be guarded against to a considerable extent by endeavoring to keep the two classes of circuits on different sides of the same street.

WHEN THE ENTIRE CIRCUIT FROM CENTRAL STATION TO BUILDING IS RUN IN UNDERGROUND CONDUITS, SECTIONS b TO m INCLUSIVE DO NOT APPLY.

b. When outside wires are run on same pole with electric light or power wires, the distance between the two inside pins of each cross-arm must not be less than twenty-six inches.

Signaling wires being smaller and more liable to break and fall, should generally be placed on the lower cross-arms.

c. Where wires are attached to the outside walls of buildings they must have an *approved* rubber insulating covering (see No. 41), and on frame buildings or frame portions of other buildings shall be supported on glass or porcelain insulators, or knobs.

d. The wires from last outside support to the cut-outs or protectors must be of copper, and must have an *approved* rubber insulation (see No. 41); must be provided with drip loops immediately outside the building and at entrance; must be kept not less than 2½ inches apart, except when brought in through approved metal cables.

e. Wires must enter building through approved non-combustible, non-absorptive, insulating bushings sloping upward from the outside.

INSTALLATIONS WHERE THE CURRENT-CARRYING PARTS OF THE APPARATUS INSTALLED ARE CAPABLE OF CARRYING INDEFINITELY A CURRENT OF TEN AMPERES.

f. An all-metallic circuit shall be provided, except in telegraph systems.

g. At the entrance of wires to buildings, *approved* single-pole cut-outs, designed for 251–600 volts potential and containing fuses rated at not over 10 amperes capacity, shall be provided for each wire. These cut-outs must not be placed in the immediate vicinity of easily ignitable stuff, or where

exposed to inflammable gases or dust or to flyings of combustible material.

h. The wires inside buildings shall be of copper not less than No. 16 B. & S. gage, and must have insulation and be supported, the same as would be required for an installation of electric light or power wiring, 0-600 volts potential.

i. The instruments shall be mounted on bases constructed of non-combustible, non-absorptive insulating material. Holes for the supporting screws must be so located, or countersunk, that there will be at least $\frac{1}{4}$ inch space, measured over the surface, between the head of the screw and the nearest live metal part.

INSTALLATIONS WHERE THE CURRENT-CARRYING PARTS OF THE APPARATUS INSTALLED ARE NOT CAPABLE OF CARRYING INDEFINITELY A CURRENT OF TEN AMPERES.

j. Must be provided with an *approved* protective device located as near as possible to the entrance of wires to building. The protector must not be placed in the immediate vicinity of easily ignitable stuff, or where exposed to inflammable gases or dust or flyings of combustible materials.

k. Wires from entrance to building to protector must be supported on porcelain insulators, so that they will come in contact with nothing except their designed supports.

l. The ground wire of the protective device shall be run in accordance with the following requirements:—

1. Shall be of copper and not smaller than No. 18 B. & S. gage.
2. Must have an *approved* insulating covering as described in No. 41, for voltages from 0 to 600, except that the preservative compound specified in No. 41, Section h may be omitted.
3. Must run in as straight a line as possible to a good permanent ground.

This may be obtained by connecting to a water or gas pipe connected to the street mains or to a ground rod or pipe driven in permanently damp earth. When connections are made to pipes, preference shall be given to water pipes. If attachment is made to gas pipe, the connection in all cases must be made between the meter and the street mains. In every case the connection shall be made as near as possible to the earth.

When the ground wire is attached to water or gas pipes, these pipes shall be thoroughly cleaned and tinned with rosin flux solder, if such a method is practicable; the ground wire shall then be wrapped tightly around the pipe and thoroughly soldered to it.

When the above method is impracticable, then, if there are fittings where a brass plug can be inserted, the ground wire shall be thoroughly soldered to it; if there are no such fittings, then the pipe shall be thoroughly cleaned and an approved ground clamp fastened to an exposed portion of the pipe and the ground wire well soldered to the ground clamp.

When the ground wire is attached to a ground rod driven into the earth, the ground wire shall be soldered to the rod in a similar manner.

Steam or hot water pipes must not be used for a protector ground.

m. The protector to be approved must comply with the following requirements:—

For Instrument Circuits of Telegraph Systems.—1. An *approved* single-pole cut-out, in each wire, designed for 2,000 volt potential, and containing fuses rated at not over one ampere capacity. When main line cut-outs are installed as called for in Section g, the instrument cut-outs may be placed between the switchboard and the instrument as near the switchboard as possible.

For All Other Systems.—1. Must be mounted on non-combustible, non-absorptive, insulating bases, so designed that when the protector is in place, all parts which may be alive will be thoroughly insulated from the wall to which the protector is attached.

2. Must have the following parts:—

A lightning arrester which will operate with a difference of potential between wires of not over 500 volts, and so arranged that the chance of accidental grounding is reduced to a minimum.

A fuse designed to open the circuit in case the wires become crossed with light or power circuits. The fuse must be able to open the circuit without arcing or serious flashing when crossed with any ordinary commercial light or power circuit.

A heat coil, if the sensitiveness of the instrument demands it, which will operate before a sneak current can damage the instrument the protector is guarding.

Heat coils are necessary in all circuits normally closed through magnet windings, which cannot indefinitely carry a current of at least 5 amperes.

The heat coil is designed to warm up and melt out with a current large enough to endanger the instruments if continued for a long time, but so small that it would not blow the fuses ordinarily found necessary for such instruments. The smaller currents are often called "sneak" currents.

3. The fuses must be so placed as to protect the arrester and heat coils, and the protector terminals must be plainly marked "line," "instrument," "ground."

An easily read abbreviation of the above words will be allowed.

**THE FOLLOWING RULES APPLY TO ALL SYSTEMS WHETHER THE WIRES
FROM THE CENTRAL OFFICE TO THE BUILDING ARE
OVERHEAD OR UNDERGROUND.**

n. Wires beyond the protector, or wires inside buildings where no protector is used, must be neatly arranged and securely fastened in place in some convenient, workmanlike manner. They must not come nearer than 6 inches to any electric light or power wire in the building unless encased in *approved* tubing so secured as to prevent its slipping out of place.

The wires would ordinarily be insulated, but the kind of insulation is not specified, as the protector is relied upon to stop all dangerous currents. Porcelain tubing or *approved* flexible tubing may be used for encasing wires where required as above.

o. Wires where bunched together in a vertical run within any building must have a fire-resisting covering sufficient to prevent the wires from carrying fire from floor to floor unless they are run either in non-combustible tubing or in a fireproof shaft, which shaft shall be provided with fire stops at each floor.

Signaling wires and electric light or power wires may be run in the same shaft, provided that one of these classes of wires is run in non-combustible tubing, or provided that when run otherwise these two classes of wires shall be separated from each other by at least 2 inches.

In no case shall signaling wires be run in the same tube with electric light or power wires.

Ordinary rubber insulation is inflammable, and when a number of wires are contained in a shaft extending through a building they afford a ready means of carrying fire from floor to floor, unless they are covered with a fire-resisting material, or unless the shaft is provided with fire stops at each floor.

65. Electric Gas Lighting.—a. Electric gas lighting must not be used on the same fixture with the electric light.

The above rule does not apply to *frictional systems* of gas lighting.

65 A. Moving Picture Machines.—a. Arc lamp used as a part of moving picture machines must be constructed similar to arc lamps of theaters, and wiring of same must not be of less capacity than No. 6 B. & S. gage. (See No. 31 A d. [1].)

b. Rheostats must conform to rehostat requirements for theater arcs. (See No. 31 A d. [1].)

c. Top reel must be encased in a steel box with hole at the bottom only large enough for film to pass through, and cover so arranged that this hole can be instantly closed. No solder to be used in the construction of this box.

d. A steel box must be used, for receiving the film after being shown, with a hole in the top only large enough for the film to pass through freely, with a cover so arranged that this hole can be instantly closed. An opening may be placed at the side of the box to take the film out, with a door hung at the top, so arranged that it cannot be entirely opened, and provided with a spring-catch to lock it closed. No solder to be used in the construction of this box.

e. The handle or crank used in operating the machine must be secured to the spindle or shaft, so that there will be no liability of its coming off and allowing the film to stop in front of lamp.

f. A shutter must be placed in front of the condenser, arranged so as to be readily closed.

g. Extra films must be kept in metal box with tight-fitting cover.

h. Machines must be operated by hand (motor-driven will not be permitted.)

i. Picture machine must be placed in an enclosure or house made of suitable fireproof material, be thoroughly ventilated and large enough for operator to walk freely on either side of or back of machine. All openings into this booth must be arranged so as to be entirely closed by doors or shutters constructed of the same or equally good fire-resisting material as the booth itself. Doors or covers must be arranged so as to be held normally closed by spring hinges or equivalent devices.

66. Insulation Resistance.—The wiring in any building must test free from grounds; i. e., the complete installation must have an insulation between conductors and between all conductors and the ground (not including attachments, sockets, receptacles, etc.) not less than that given in the following table:—

Up to	5 amperes.....	4,000,000 ohms.
"	10 ".....	2,000,000 "
"	25 ".....	800,000 "
"	50 ".....	400,000 "
"	100 ".....	200,000 "
"	200 ".....	100,000 "
"	400 ".....	50,000 "
"	800 ".....	25,000 "
"	1,600 ".....	12,500 "

The test must be made with all cut-outs and safety devices in place. If the lamp sockets, receptacles, electroliers, etc., are also connected, only one-half of the resistances specified in the table will be required.

67. Soldering Fluid.—a. The following formula for soldering fluid is suggested:—

Saturated solution of zinc chloride.....	5 parts.
Alcohol.....	4 parts.
Glycerine.....	1 part.

Class F.—MARINE WORK.

68. Generators.—a. Must be located in a dry place.

b. Must have their frames insulated from their bed-plates.

c. Must each be provided with a waterproof cover.

d. Must each be provided with a name-plate, giving the maker's name, the capacity in volts and amperes, and the normal speed in revolutions per minute.

69. Wires.—a. Must be supported in *approved* moulding or conduit, except at switchboards and for portables.

Special permission may be given for deviation from this rule in dynamo rooms.

b. Must have no single wire larger than No. 12 B. & S. gage. Wires to be stranded when greater carrying capacity is required. No single solid wire smaller than No. 14 B. & S. gage, except in fixture wiring, to be used.

Stranded wires must be soldered before being fastened under clamps or binding screws, and when they have a conductivity greater than that of No. 8 B. & S. gage copper wire they must be soldered into lugs.

c. Splices or taps in conductors must be avoided as far as possible. Where it is necessary to make them they must be so spliced or joined as to be both mechanically and electrically secure without solder. They must then be soldered, to insure preservation, covered with an insulating compound equal to the insulation of the wire, and further protected by a waterproof tape. The joint must then be coated or painted with a waterproof compound.

All joints must be soldered unless made with some form of *approved* splicing device.

For Moulding Work.—d. Must have an *approved* insulating covering.

The insulation for conductors, to be approved, must be at least 3-32 of an inch in thickness and be covered with a substantial waterproof braid.

The physical characteristics shall not be affected by any change in temperature up to 200° Fahrenheit (93° Centigrade). After two weeks' submersion in salt water at 70° Fahrenheit (21° Centigrade), it must show an insulation resistance of 100 megohms per mile after three minutes' electrification with 550 volts.

e. Must have, when passing through water-tight bulkheads and through all decks, a metallic stuffing tube lined with hard rubber. In case of deck tubes, they must be boxed near deck to prevent mechanical injury.

f. Must be bushed with hard rubber tubing, $\frac{1}{8}$ of an inch in thickness, when passing through beams and non-water-tight bulkheads.

For Conduit Work.—g. Must have an *approved* insulating covering.

The insulation for conductors, for use in lined conduits, to be approved, must be at least 3-32 of an inch in thickness and be covered with a substantial waterproof braid. The physical characteristics shall not be affected by any change in temperature up to 200° Fahrenheit (93° Centigrade).

After two weeks' submersion in salt water at 70° Fahrenheit (21° Centigrade), it must show an insulation resistance of 100 megohms per mile after three minutes' electrification with 550 volts.

For unlined metal conduits, conductors must conform to the specifications given for lined conduits, and in addition have a second outer fibrous covering at least $\frac{1}{32}$ of an inch in thickness and sufficiently tenacious to withstand the abrasion of being hauled through the metal conduit.

h. Must not be drawn in until the mechanical work on the conduit is completed and same is in place.

i. Where run through coal bunkers, boiler rooms, and where they are exposed to severe mechanical injury, must be encased in *approved* conduit.

70. Portable Conductors.—a. Must be made of two stranded conductors each having a carrying capacity equivalent to not less than No. 14 B. & S. gage, and each covered with an *approved* insulation and covering.

Where not exposed to moisture or severe mechanical injury, each stranded conductor must have a solid insulation at least 1-32 of an inch in thickness, and must show an insulation resistance between conductors, and between either conductor and the ground, of at least 50 megohms per mile after two weeks' submersion in water at 70° Fahrenheit (21° Centigrade), and be protected by a slow-burning, tough-braided outer covering.

Where exposed to moisture and mechanical injury (as for use on decks, holds and fire-rooms), each stranded conductor shall have a solid insulation, to be approved, of at least 1-32 of an inch in thickness and protected by a tough braid. The two conductors shall then be stranded together, using a jute filling. The whole shall then be covered with a layer of flax, either woven or braided, at least 1-32 of an inch in thickness and treated with a non-inflammable, waterproof compound. After one week's submersion in water at 70° Fahrenheit (21° Centigrade), it must show an insulation between the two conductors, or between either conductor and the ground, of 50 megohms per mile.

71. Bell or Other Wires—a. Must never be run in same duct with lighting or power wires.

72. Table of Capacity of Wires.—

B. & S. G.	Area Actual C. M.	No. of Strands.	Size of Strands. B. & S. G.	Amperes.
19	1,288	..	..	..
18	1,624	..	..	3
17	2,048	..	..	..
16	2,583	..	..	6
15	3,257	..	..	..
14	4,107	..	..	12
12	6,530	..	..	17
..	9,016	7	19	21
..	11,368	7	18	25
..	14,336	7	17	30
..	18,081	7	16	35
..	22,799	7	15	40
..	30,856	19	18	50

B. & S. G.	Area Actual C. M.	No. of Strands	Size of Strands B. & S. G.	Amperes.
..	38,912	19	17	60
..	49,077	19	16	70
..	60,088	37	18	85
..	75,776	37	17	100
..	99,064	61	18	120
..	124,928	61	17	145
..	157,563	61	16	170
..	198,677	61	15	200
..	250,527	61	14	235
..	296,387	91	15	270
..	373,737	91	14	320
..	413,639	127	15	340

When greater conducting area than that of No. 12 B. & S. gage is required, the conductor shall be stranded in a series of 7, 19, 37, 61, 91, or 127 wires, as may be required; the strand consisting of one central wire, the remainder laid around it concentrically, each layer to be twisted in the opposite direction from the preceding.

73. Switchboards.—a. Must be made of non-combustible, non-absorptive insulating material, such as marble or slate.

b. Must be kept free from moisture, and must be located so as to be accessible from all sides.

c. Must have a main switch, main cut-out and ammeter for each generator.

Must also have a voltmeter and ground detector.

d. Must have a cut-out and switch for each side of each current leading from board.

e. Must be wired with conductors having an insulation as required for moulding or conduit work and covered with a substantial flame-proof braid.

74. Resistance Boxes.—(For construction rules, see No. 60.) a. Must be located on switchboard or away from combustible material. When not placed on switchboard they must be mounted on non-inflammable, non-absorptive insulating material.

75. Switches.—(For construction rules, see No. 51) a. When exposed to dampness, they must be enclosed in a water-tight case.

b. Must be of the knife pattern when located on switchboard.

c. Must be provided so that each freight compartment may be separately controlled.

76. Cut-Outs.—(For construction rules, see No. 52.) a. Must be placed at every point where a change is made in the size of the wire (unless the cut-out in the larger wire will protect the smaller).

b. In such places as upper decks, holds, cargo spaces and fire-rooms, a water-tight and fire-proof cut-out may be used, connecting directly to mains when such cut-out supplies circuits requiring not more than 660 watts energy.

c. When placed anywhere except on switchboards and certain places, as cargo spaces, holds, fire-rooms, etc., where it is impossible to run from center of distribution, they must be in a cabinet lined with fire-resisting material.

d. Except for motors, searchlights and diving lamps must be so placed that no group of lamps, requiring a current of more than 660 watts, shall ultimately be dependent upon one cut-out.

77. Fixtures.—a. Must be mounted on blocks made from well-seasoned lumber treated with two coats of white lead or shellac.

b. Where exposed to dampness, the lamp must be surrounded by a vapor-proof globe.

c. Where exposed to mechanical injury, the lamp must be surrounded by a globe protected by a stout wire guard.

d. Must be wired with same grade of insulation as portable conductors which are not exposed to moisture or mechanical injury.

e. Ceiling fixtures over two feet in length must be provided with stay chains.

78. Sockets.—(For construction rules, see No. 55.)

79. Wooden Mouldings.—(For construction rules, see No. 50.)

a. Where moulding is run over rivets, beams, etc., a backing strip must first be put up and the moulding secured to this.

b. Capping must be secured by brass screws.

80. Interior Conduits.—(For installation rules, see No. 25.) (For construction rules, see No. 49.)

81. Signal Lights.—a. Must be provided with *approved* telltale board, located preferably in pilot house, which will immediately indicate a burned-out lamp.

82. Motors.—a. Must be wired under the same precautions as with a current of same volume and potential for lighting. The motor and resistance box must be protected by a double-pole cut-out and controlled by a double-pole switch, except in cases where one-quarter horse power or less is used.

The motor leads or branch circuits must be designed to carry a current at least 25 per cent greater than that for which the motor is rated, in order to provide for the inevitable occasional overloading of the motor, and the increased current required in starting, without overfusing the wires, but where the wires under this rule would be overfused, in order to provide for the starting current, as in the case of many of the alternating current motors, the wires must be of such size as to be properly protected by these larger fuses.

In general, motors should preferably have no exposed live parts.

b. Must be thoroughly insulated. Where possible, should be set on base frames made from filled, hard, dry wood and raised above surrounding deck. On hoists and winches they must be insulated from bed-plates by hard rubber, fiber or similar insulating material.

c. Must be covered with a waterproof cover when not in use.

d. Must each be provided with a name-plate, giving maker's name, the capacity in volts and amperes, and the normal speed in revolutions per minute.

83. Insulation Resistance.—The wiring in any vessel must test free from grounds; *i. e.*, the complete installation must have an insulation between conductors and between all conductors and the ground (not including attachments, sockets, receptacles, etc.), of not less than the following:—

Up to	25 amperes.....	800,000 ohms.
"	50 "	400,000 "
"	100 "	200,000 "
"	200 "	100,000 "
"	400 "	50,000 "
"	800 "	25,000 "
"	1,600 "	12,500 "

All cut-outs and safety devices in place in the above.

Where lamp sockets, receptacles and electrolliers, etc., are connected, one-half of the above will be required.

ELECTRICAL STANDARDIZATION.

STANDARDIZATION RULES OF THE AM. INST. OF ELEC. ENGRS.

Approved by the Board of Directors, June 21, 1907.

Accepted by the 24th Annual Convention, June 27, 1907.

I.—DEFINITIONS AND TECHNICAL DATA.

- 1 *Note*.—The following definitions and classifications are intended to be practically descriptive and not scientifically rigid.

A.—DEFINITIONS. CURRENTS.

- 2 A *Direct Current* is a unidirectional current.
 3 A *Continuous Current* is a steady, or non-pulsating, direct current.
 4 A *Pulsating Current* is a current equivalent to the superposition of an alternating current upon a continuous current.
 5 An *Alternating Current* is a current which, when plotted, consists of half-waves of equal area in successively opposite directions from the zero line.
 6 An *Oscillating Current* is a current alternating in direction, and of decreasing amplitude.

B.—DEFINITIONS. ROTATING MACHINES.

- 7 A *Generator* transforms mechanical power into electrical power.
 8 A *Direct-Current Generator* produces a direct current that may or may not be continuous.
 9 An *Alternator* or *Alternating-Current Generator* produces alternating current, either single-phase or polyphase.
 10 A *Polyphase Generator* produces currents differing symmetrically in phase; such as two-phase currents, in which the terminal voltages on the two circuits differ in phase by 90° ; or three-phase currents, in which the terminal voltages on the three circuits differ in phase by 120° .
 11 A *Double-Current Generator* produces both direct and alternating currents.
 12 A *Motor* transforms electrical into mechanical power.
 13 A *Booster* is a machine inserted in series in a circuit to change its voltage. It may be driven by an electric motor (in which case it is termed a motor-booster) or otherwise.
 14 A *Motor-Generator* is a transforming device consisting of a motor mechanically connected to one or more generators.
 15 A *Dynamotor* is a transforming device combining both motor and generator action in one magnetic field, with two armatures; or with an armature having two separate windings and independent commutators.
 16 A *Converter* is a machine employing mechanical rotation in changing electrical energy from one form to another. A converter may belong to either of several types, as follows:
 17 a. A *Direct-Current Converter* converts from a direct current to a direct current.
 18 b. A *Synchronous Converter* (commonly called a rotary converter) converts from an alternating to a direct current, or *vice versa*.
 19 c. A *Motor-Converter* is a combination of an induction motor with a synchronous converter, the secondary of the former feeding the armature of the latter with current at some frequency other than the impressed frequency; i. e., it is a synchronous converter concatenated with an induction motor.
 20 d. A *Frequency-Converter* converts from an alternating-current system of one frequency to an alternating-current system of another frequency, with or without a change in the number of phases or in voltages.
 21 e. A *Rotary Phase Converter* converts from an alternating-current system of one or more phases to an alternating-current system of a different number of phases, but of the same frequency.

C.—DEFINITIONS. STATIONARY INDUCTION APPARATUS.

- 22 *Stationary Induction Apparatus* change electric energy to electric energy through the medium of magnetic energy. They comprise several forms, distinguished as follows:

- 23 a. In *Transformers* the primary and secondary windings are insulated from one another.
- 24 b. In *Auto-Transformers*, also called compensators, a part of the primary winding is used as a secondary winding, or conversely.
- 25 c. In *Potential Regulators* a coil is in shunt and a coil is in series with the circuit, so arranged that the ratio of transformation between them is variable at will. They are of the following three classes:
- 26 (a) *Compensator Potential Regulators* in which a number of turns of one of the coils are adjustable.
- 27 (b) *Induction Potential Regulators* in which the relative positions of the primary and secondary coils are adjustable.
- 28 (c) *Magneto Potential Regulators* in which the direction of the magnetic flux with respect to the coils is adjustable.
- 29 d. *Reactors*, or *Reactance Coils*, formerly called choking coils, are a form of stationary induction apparatus used to produce reactance or phase displacement.

D.—GENERAL CLASSIFICATION OF APPARATUS.

- 30 *Commutating Machines*. Under this head may be classed the following: Direct current generators; direct-current motors; direct-current boosters; motor-generators; dynamos; converters, compensators or balancers; closed-coil arc machines, and alternating-current commutating motors.
- 31 Commutating machines may be further classified as follows:
- 32 a. *Direct-Current Commutating Machines*, which comprise a magnetic field of constant polarity, a closed-coil armature, and a multisegmental commutator connected therewith.
- 33 b. *Alternating-Current Commutating Machines*, which comprise a magnetic field of alternating polarity, a closed-coil armature, and a multisegmental commutator connected therewith.
- 34 c. *Synchronous Commutating Machines*, which comprise synchronous converters, motor converters and double-current generators.
- 35 *Synchronous Machines*, which comprise a constant magnetic field, and an armature receiving or delivering alternating-currents in synchronism with the motion of the machine; i.e., having a frequency equal to the product of the number of pairs of poles and the speed of the machine in revolutions per second.
- 36 *Stationary Induction Apparatus*, which includes transformers, auto-transformers, potential regulators, and reactors or reactance coils.
- 37 *Rotary Induction Apparatus*, or *Induction Machines*, which include apparatus wherein the primary and secondary windings rotate with respect to each other; i.e., induction motors, induction generators, frequency converters, and rotary phase converters.
- 38 *Unipolar or Acyclic Machines*, in which the voltage generated in the active conductors maintains the same direction with respect to those conductors.
- 39 *Rectifying Apparatus, Pulsating-Current Generators.*
- 40 *Electrostatic Apparatus*, such as condensers, etc.
- 41 *Electrochemical Apparatus*, such as batteries, etc.
- 42 *Electrothermal Apparatus*, such as rheostats, heaters, etc.
- 43 *Protective Apparatus*, such as fuses, lightning arresters, etc.
- 44 *Luminous Sources.*

E.—MOTORS. SPEED CLASSIFICATION.

- 45 *Motors* may, for convenience, be classified with reference to their speed characteristics as follows:
- 46 a. *Constant-Speed Motors*, in which the speed is either constant or does not materially vary; such as synchronous motors, induction motors with small slip, and ordinary direct-current shunt motors.
- 47 b. *Multispeed Motors* (two-speed, three-speed, etc.), which can be operated at any one of several distinct speeds, these speeds being practically independent of the load, such as motors with two armature windings.
- 48 c. *Adjustable-Speed Motors*, in which the speed can be varied gradually over a considerable range; but when once adjusted remains practically unaffected by the load, such as shunt motors designed for a considerable range of field variation.
- 49 d. *Varying-Speed Motors*, or motors in which the speed varies with the load, decreasing when the load increases; such as series motors.

F.—DEFINITION AND EXPLANATION OF TERMS.

(I) LOAD FACTOR.

- 50 The *Load Factor* of a machine, plant or system is the ratio of the average power to the maximum power during a certain period of time. The average power is taken over a certain interval of time, such as a day or a year, and the maximum is taken over a short interval of the maximum load within that interval.

- 51 In each case the interval of maximum load should be definitely specified. The proper interval is usually dependent upon local conditions and upon the purpose for which load factor is to be determined.

(II) NON-INDUCTIVE LOAD AND INDUCTIVE LOAD.

- 52 A non-inductive load is a load in which the current is in phase with the voltage across the load.

- 53 An inductive load is a load in which the current lags behind the voltage across the load. A load in which the current leads the voltage across the load is sometimes called in anti-inductive load.

(III) POWER-FACTOR AND REACTIVE-FACTOR.

- 54 The *Power-Factor* in alternating-current circuits or apparatus is the ratio of the electric power in watts to the apparent power in volt-amperes. It may be expressed as follows:

$$\frac{\text{true power}}{\text{apparent power}} = \frac{\text{watts}}{\text{volt-amperes}} = \frac{\text{energy current}}{\text{total current}} = \frac{\text{energy voltage}}{\text{total voltage}}$$

- 55 The *Reactive-Factor* is the ratio of the wattless volt-amperes (*i.e.*, the product of the wattless component of current by voltage, or wattless component of voltage by current) to the total amperes. It may be expressed as follows:

$$\frac{\text{wattless volt-amperes}}{\text{total volt-amperes}} = \frac{\text{wattless current}}{\text{total current}} = \frac{\text{wattless voltage}}{\text{total voltage}}$$

- 56 *Power-Factor* and *Reactive-Factor* are related as follows:

If p = power-factor, q = reactive-factor, then with sine waves of voltage and current,

$$p^2 + q^2 = 1.$$

With distorted waves of voltage and current,

$$p^2 + q^2 = \text{or} < 1.$$

(IV) SATURATION-FACTOR.

- 57 The *Saturation-Factor* of a machine is the ratio of a small percentage increase in field excitation to the corresponding percentage increase in voltage thereby produced. The saturation-factor is, therefore, a criterion of the degree of saturation attained in the magnetic circuits at any excitation selected. Unless otherwise specified, however, the saturation-factor of a machine refers to the excitation existing at normal rated speed and voltage. It is determined from measurements of saturation made on open circuit at rated speed.

- 58 The *Percentage of Saturation* of a machine at any excitation may be found from its saturation curve of generated voltage as ordinates, against excitation as abscissas, by drawing a tangent to the curve at the ordinate corresponding to the assigned excitation, and extending the tangent to intercept the axis of ordinates drawn through the origin. The ratio of the intercept on this axis to the ordinate at the assigned excitation, when expressed in percentage, is the percentage of saturation and is independent of the scale selected for excitation and voltage. This ratio is equal to the reciprocal of the saturation-factor at the same excitation, deducted from unity. Thus, if f be the saturation-factor and p the percentage of saturation ratio,

$$p = 1 - \frac{1}{f}.$$

(V) VARIATION AND PULSATION.

- 59 The *Variation in Prime Movers* which do not give an absolutely uniform rate of rotation or speed, as in reciprocating steam engines, is the maximum angular displacement in position of the revolving member

expressed in degrees, from the position it would occupy with uniform rotation, and with one revolution taken as 360° .

- 60 The *Pulsation in Prime Movers* is the ratio of the difference between the maximum and minimum velocities in an engine-cycle to the average velocity.
- 61 The *Variation in Alternators* or alternating-current circuits in general is the maximum difference in phase of the generated voltage wave from a wave of absolutely constant frequency, expressed in electrical degrees (one cycle equals 360°) and may be due to the variation of the prime mover.
- 62 The *Pulsation in Alternators* or alternating-current circuits, in general, is the ratio of the difference between maximum and minimum frequency during an engine cycle to the average frequency.
- 63 *Relation of Variation in prime mover and alternator:*
- 64 If n = number of pairs of poles, the variation of an alternator is n times the variation of its prime mover, if direct-connected, and n/p times the variation of the prime mover if rigidly connected thereto in the velocity ratio p .

II.—PERFORMANCE SPECIFICATIONS AND TESTS.

A.—RATING.

- 65 *Rating by Output.* All electrical apparatus should be rated by output and not by input. Generators, transformers, etc., should be rated by electrical output; motors by mechanical output.
- 66 *Rating in Kilowatts.* Electrical power should be expressed in kilowatts, except when otherwise specified.
- 67 *Apparent Power, Kilovolt-Amperes.* Apparent power in alternating-current circuits should be expressed in kilovolt-amperes as distinguished from real power in kilowatts. When the power factor is 100 per cent., the apparent power in kilovolt-amperes is equal to the kilowatts.
- 68 The *Rated (Full Load) Current* is that current which, with the rated terminal voltage, gives the rated kilowatts, or the rated kilovolt-amperes. In machines in which the rated voltage differs from the no-load voltage, the rated current should refer to the former.
- 69 *Determination of Rated Current.* The rated current may be determined as follows: If P = rating in watts, or apparent watts if the power factor be other than 100 per cent., and E = full-load terminal voltage, the rated current per terminal is:
- 70 $I = \frac{P}{E}$ in a direct-current machine or single-phase alternator.
- 71 $I = \frac{1}{\sqrt{3}} \frac{P}{E}$ in a three-phase alternator.
- 72 $I = \frac{1}{2} \frac{P}{E}$ in a two-phase alternator.
- 73 *Normal Conditions.* The rating of machines or apparatus should be based upon certain normal conditions to be assumed as standard, or to be specified. These conditions include voltage, current, power-factor, frequency, wave shape and speed; or such of them as may apply in each particular case. Performance tests should be made under these standard conditions unless otherwise specified.
- 74 *a. Power Factor.* Alternating-current apparatus should be rated in kilowatts, at 100 per cent power factor; i.e., with current in phase with terminal voltage, unless a phase displacement is inherent in the apparatus or is specified. If a power factor other than 100 per cent is specified, the rating should be expressed in kilovolt-amperes and power factor, at rated load.
- 75 *b. Wave Shape.* In determining the rating of alternating-current machines or apparatus, a sine wave shape of alternating current and voltage is assumed, except where a distorted wave shape is inherent to the apparatus. See Secs. 79-83.
- 76 *Fuses.* The rating of a fuse should be the maximum current which it will continuously carry.
- 77 *Circuit-Breakers.* The rating of a circuit-breaker should be the maximum current which it is designed to carry continuously.

- 78 *a. Note.* In addition thereto, the maximum current and voltage at which a fuse or a circuit-breaker will open the circuit should be specified. It is to be noted that the behavior of fuses and of circuit-breakers is much influenced by the amount of electric power available on the circuit.

B.—WAVE SHAPE.

- 79 The *Sine Wave* should be considered as standard, except where a difference in the wave form from the sinusoidal is inherent in the operation of the apparatus.
- 80 A *Maximum Deviation* of the wave from sinusoidal shape not exceeding 10 per cent is permissible, except when otherwise specified.
- 81 The *Deviation* of wave form from the sinusoidal is measured by determining the form by oscillograph or wave meter, computing therefrom the equivalent sine wave of equal length, superposing the latter upon the observed wave in such a manner as to give least difference, and then dividing the maximum difference at any ordinate by the maximum value of the equivalent sine wave.
- 82 The *Equivalent Sine Wave* is a sine wave having the same frequency and the same effective or r.m.s. (root of mean square) value as the actual wave.
- 83 *Non-Sine Waves.* The phase displacement between two waves which are not sine waves, is that phase displacement between their equivalent sine waves which would give the same average product of instantaneous values as the actual waves; *i.e.*, the same electro-dynamometer reading.

C.—EFFICIENCY.

(I)—DEFINITIONS.

- 84 The *Efficiency* of an apparatus is the ratio of its net power output to its gross power input.
- 85 *a. Note.* An exception should be noted in the case of storage batteries or apparatus for storing energy in which the efficiency, unless otherwise qualified, should be understood as the ratio of the energy output to the energy intake in a normal cycle. An exception should also be noted in the case of luminous sources.
- 86 *Apparent Efficiency.* In apparatus in which a phase displacement is inherent to their operation, apparent efficiency should be understood as the ratio of the net power output to volt-ampere input.
- 87 *a. Note.* Such apparatus comprise induction motors, reactive synchronous converters, synchronous converters controlling the voltage of an alternating-current system, self-exciting synchronous motors, potential regulators and open magnetic circuit transformers, etc.
- 88 *b. Note.* Since the apparent efficiency of apparatus delivering electric power depends upon the power-factor of the load, the apparent efficiency, unless otherwise specified, should be referred to a load power-factor of unity.

(II)—DETERMINATION OF EFFICIENCY.

- 89 *Methods.* Efficiency may be determined by either of two methods, *viz.*: by measurement of input and output; or, by measurement of losses.
- 90 *a. Method of Input and Output.* The input and output may both be measured directly. The ratio of the latter to the former is the efficiency.
- 91 *b. Method by Losses.* The losses may be measured either collectively or individually. The total losses may be added to the output to derive the input, or subtracted from the input to derive the output.
- 92 *Comparison of Methods.* The output and input method is preferable with small machines. When, however, as in the case of large machines, it is impracticable to measure the output and input; or when the percentage of power loss is small and the efficiency is nearly unity, the method of determining efficiency by measuring the losses should be followed.
- 93 *Electric Power* should be measured at the terminals of the apparatus. In tests of polyphase machines, the measurement of power should not be confined to a single circuit but should be extended to all the circuits in order to avoid errors of unbalanced loading.
- 94 *Mechanical Power* in machines should be measured at the pulley, gearing, coupling, etc., thus excluding the loss of power in said pulley gearing or coupling, but including the bearing friction and windage. The

magnitude of bearing friction and windage may be considered, with constant speed, as independent of the load. The loss of power in the belt and the increase of bearing friction due to belt tension should be excluded. Where, however, a machine is mounted upon the shaft of a prime mover, in such a manner that it cannot be separated therefrom, the frictional losses in bearings and in windage, which ought, by definition, to be included in determining the efficiency, should be excluded, owing to the practical impossibility of determining them satisfactorily.

- 95 In *Auxiliary Apparatus*, such as an exciter, the power lost in the auxiliary apparatus should not be charged to the principal machine, but to the plant consisting of principal machine and auxiliary apparatus taken together. The plant efficiency in such cases should be distinguished from the machine efficiency.
- 96 *Normal Conditions*. Efficiency tests should be made under normal conditions herein set forth and which are to be assumed as standard. These conditions include voltage, current, power-factor, frequency, wave shape, speed and barometric pressure, temperature, or such of them as may apply in each particular case. Performance tests should be made under these standard conditions unless otherwise specified. See Secs. 73-75.
- 97 *a. Temperature*. The efficiency of all apparatus, except such as may be intended for intermittent service, should be either measured at, or reduced to, the temperature which the apparatus assumes under continuous operation at rated load, referred to a room temperature of 25° C. See Secs. 287-292.
- 98 With apparatus intended for intermittent service, the efficiency should be determined at the temperature assumed under specified conditions.
- 99 *b. Power Factor*. In determining the efficiency of alternating-current apparatus, the electric power should be measured when the current is in phase with the voltage, unless otherwise specified, except when a definite phase difference is inherent in the apparatus, as in induction motors, induction generators, frequency converters, etc.
- 100 *c. Wave Shape*. In electrical apparatus, the sine wave should be considered as standard, except where a difference in the wave form from the sinusoidal is inherent in the operation of the apparatus. See Secs. 79-83.

(III)—MEASUREMENT OF LOSSES.

- 101 *Losses*. The usual sources of losses in electrical apparatus and the methods of determining these losses are as follows:

(A)—BEARING FRICTION AND WINDAGE.

- 102 The magnitude of bearing friction and windage (which may be considered as independent of the load) is conveniently measured by driving the machine from an independent motor, the output of which may be suitably determined. See Sec. 94.

(B)—COMMUTATOR BRUSH FRICTION.

- 103 The magnitude of the commutator brush friction (which may be considered as independent of the load) is determined by measuring the difference in power required for driving the machine with brushes on and with brushes off (the field being unexcited).

(C)—COLLECTOR-RING BRUSH FRICTION.

- 104 Collector-ring brush friction may be determined in the same manner as commutator brush friction. It is usually negligible.

(D)—MOLECULAR MAGNETIC FRICTION AND EDDY CURRENTS.

- 105 These losses include those due to molecular magnetic friction and eddy currents in iron and copper and other metallic parts, also the losses due to currents in the cross-connections of cross-connected armatures.

- 106 In *Machines* these losses should be determined on open circuit and at a voltage equal to the rated voltage + $I r$ in a generator, and - $I r$ in a motor, where I denotes the current strength and r denotes the internal resistance of the machine. They should be measured at the correct speed and voltage, since they do not usually vary in any definite proportion to the speed or to the voltage.

107 *Note.* The *Total Losses* in bearing friction and windage, brush friction, magnetic friction and eddy currents can, in general, be determined by a single measurement by driving the machine with the field excited, either as a motor, or by means of an independent motor.

108 *Retardation Method.* The no-load iron, friction, and windage losses may be segregated by the Retardation Method, in which the generator should be brought up to full speed (or, if possible, to about 10 per cent. above full speed) as a motor, and, after cutting off the driving power and excitation, frequent readings should be taken of speed and time, as the machine slows down, from which a speed-time curve can be plotted. A second curve should be taken in the same manner, but with full field excitation; from the second curve the iron losses may be found by subtracting the losses found in the first curve.

109 The speed-time curves can be plotted automatically by belting a small separately excited generator (say 1/10 kw.) to the generator shaft and connecting it to a recording voltmeter. When the retardation method is not feasible, the frictional losses in bearings and in windage, which ought, by definition, to be included in determining the efficiency, may be excluded; but this should be expressly stated.

(E)—ARMATURE-RESISTANCE LOSS.

110 This loss may be expressed by $p I^2 r$; where r = resistance of one armature circuit or branch, I = the current in such armature circuit or branch, and p = the number of armature circuits or branches.

(F)—COMMUTATOR BRUSH AND BRUSH-CONTACT RESISTANCE LOSS.

111 It is desirable to point out that with carbon brushes these losses may be considerable in low-voltage machines.

(G)—COLLECTOR-RING AND BRUSH-CONTACT RESISTANCE LOSS.

112 This loss is usually negligible, except in machines of extremely low voltage or in unipolar machines.

(H)—FIELD EXCITATION LOSS.

113 With separately excited fields, the loss of power in the resistance of the field coils alone should be considered. With either shunt- or series-field windings, however, the loss of power in the accompanying rheostat should also be included, the said rheostat being considered as an essential part of the machine, and not as separate auxiliary apparatus.

(I)—LOAD LOSSES.

114 The load losses may be considered as the difference between the total losses under load and the sum of the losses above specified.

115 *a. In Commutating Machines* of small field distortion, the load losses are usually trivial and may, therefore, be neglected. When, however, the field distortion is large, as is shown, for instance, by the necessity for shifting the brushes between no load and full load, or with variations of load, these load losses may be considerable, and should be taken into account. In this case the efficiency may be determined either by input and output measurements, or the load losses may be estimated by the method of Sec. 116.

116 *b. Estimation of Load Losses.* While the load losses cannot well be determined individually, they may be considerable and, therefore, their joint influence should be determined by observation. This can be done by operating the machine on short-circuit and at full-load current, that is, by determining what may be called the "short-circuit core loss." With the low field intensity and great lag of current existing in this case, the load losses are usually greatly exaggerated.

117 One-third of the short-circuit core loss may, as an approximation, and in the absence of more accurate information, be assumed as the load loss.

(IV)—EFFICIENCY OF DIFFERENT TYPES OF APPARATUS.

(A)—DIRECT-CURRENT COMMUTATING MACHINES.

118 *In Direct-Current Commutating Machines* the losses are:

119 *a. Bearing Friction and Windage.* See measurement of Losses (A). Sec. 102.

- 120 *b. Molecular Magnetic Friction and Eddy Currents.* See measurement of Losses (D) Sec. 105.
- 121 *c. Armature Resistance Losses.* See Measurement of Losses (E), Sec. 110.
- 122 *d. Commutator Brush Friction.* See Measurement of Losses (B), Sec. 103.
- 123 *e. Commutator Brush and Brush Contact Resistance.* See Measurement of Losses (F), Sec. 111.
- 124 *f. Field Excitation Loss.* See Measurement of Losses (H), Sec. 113.
- 125 *g. Load Losses.* See Measurement of Losses (I), Sec. 114.
- 126 *Note.* *b* and *c* are losses in the armature or "armature losses"; *d* and *e* "commutator losses"; *f* "field losses."

(B)—ALTERNATING-CURRENT COMMUTATING MACHINES.

- 127 In *Alternating-Current Commutating Machines*, the losses are:
- 128 *a. Bearing Friction and Windage.* See Measurement of Losses (A), Sec. 102.
- 129 *b. Rotation Loss*, measured with the machine at open circuit, the brushes on the commutator, and the field excited by alternating current when driving the machine by a motor.
- 130 This loss includes molecular magnetic friction, and eddy currents, caused by rotation through the magnetic field, I^2r losses in cross-connections of cross-connected armatures, I^2r and other losses in armature-coils and armature-leads which are short-circuited by the brushes as far as these losses are due to rotation.
- 131 *c. Alternating or Transformer Loss.* These losses are measured by wattmeter in the field circuit, under the conditions of test *b*. They include molecular magnetic friction and eddy-currents due to the alternation of the magnetic field, I^2r losses in cross-connections of cross-connected armatures, I^2r and other losses in armature coil and commutator leads which are short-circuited by the brushes, as far as these losses are due to the alteration of the magnetic flux.
- 132 The losses in armature coils and commutator leads short-circuited by the brushes, can be separated in *b*, and *c*, from the other losses, by running the machine with and without brushes on the commutator.
- 133 *d. I^2r Loss, Other Load Losses* in armature and compensating winding and I^2r loss of brushes, measured by wattmeter connected across the armature and compensating winding.
- 134 *e. Field Excitation Loss.* See Measurement of Losses (H), Sec. 113.
- 135 *f. Commutator Brush-Friction.* See measurement of Losses (B), Sec. 103.

(C)—SYNCHRONOUS COMMUTATING MACHINES.

- 136 1. In *Double-Current Generators*, the efficiency of the machine should be determined as a direct-current generator, and also as an alternating-current generator. The two values of efficiency may be different, and should be clearly distinguished.
- 137 2. In *Converters* the losses should be determined when driving the machine by a motor. These losses are:
- 138 *a. Bearing Friction and Windage.* See Measurement of Losses (A), Sec. 102.
- 139 *b. Molecular Magnetic Friction and Eddy Currents.* See Measurement of Losses (D), Sec. 105.
- 140 *c. Armature Resistance Loss.* This loss in the armature is qI^2r , where I =direct current in armature, r =armature resistance and q , a factor which is equal to 1.47 in single-circuit single-phase, 1.15 in double-circuit single-phase, 0.59 in three-phase, 0.39 in two-phase, and 0.27 in six-phase converters.
- 141 *d. Commutator-Brush Friction.* See Measurement of Losses (B), Sec. 103.
- 142 *e. Collector-Ring Brush Friction.* See Measurement of Losses (C) Sec. 104.
- 143 *f. Commutator-Brush and Brush-Contact Resistance Loss.* See Measurement of Losses (F), Sec. 111.
- 144 *g. Collector-Ring Brush-Contact Resistance Loss.* See Measurement of Losses (G), Sec. 112.
- 145 *h. Field Excitation Loss.* See Measurement of Losses (H), Sec. 103.
- 146 *i. Load Losses.* These can generally be neglected, owing to the absence of field distortion.

- 147 3. *The Efficiency of Two Similar Converters* may be determined by operating one machine as a converter from direct to alternating, and the other as a converter from alternating to direct, connecting the alternating sides together, and measuring the difference between the direct-current input, and the direct-current output. This process may be modified by returning the output of the second machine through two boosters into the first machine and measuring the losses. Another modification is to supply the losses by an alternator between the two machines, using potential regulators.

(D)—SYNCHRONOUS MACHINES.

- 148 In *Synchronous Machines* the losses are:
 149 a. *Bearing Friction and Windage*. See Measurement of Losses (A),
 Sec. 102.
 150 b. *Molecular Magnetic Friction and Eddy Currents*. See Measure-
 ment of Losses (D), Sec. 105.
 151 c. *Armature Resistance Loss*. See Measurement of Losses (E),
 Sec. 110.
 152 d. *Collector-Ring Brush Friction*. See Measurement of Losses (C),
 Sec. 104.
 153 e. *Collector-Ring Brush Contact Resistance Loss*. See Measurement
 of Losses (G), Sec. 112.
 154 f. *Field Excitation Loss*. See Measurement of Losses (H), Sec. 113.
 155 g. *Load Losses*. See Measurement of Losses (I), Sec. 114.

(E)—STATIONARY INDUCTION APPARATUS.

- 156 In *Stationary Induction Apparatus*, the losses are:
 157 a. *Molecular Magnetic Friction and Eddy Currents* measured at
 open secondary circuit, rated frequency, and at rated voltage— I_r ,
 where I = rated current, r = resistance of primary circuit.
 158 b. *Resistance Losses*, the sum of the I^2r losses in the primary and
 in the secondary windings of a transformer, or in the two sections of the
 coil in a compensator or auto-transformer, where I = rated current in
 the coil or section of coil, and r = resistance.
 159 c. *Load Losses*, i. e., eddy currents in the iron and especially in the
 copper conductors, caused by the current at rated load. For practical
 purposes they may be determined by short-circuiting the secondary of
 the transformer and impressing upon the primary a voltage sufficient
 to send rated load current through the transformer. The loss in the
 transformer under these conditions measured by wattmeter gives the
 load losses + I^2r losses in both primary and secondary coils.
 160 In *Closed Magnetic Circuit Transformers*, either of the two circuits
 may be used as primary when determining the efficiency.
 161 In *Potential Regulators*, the efficiency should be taken at the maxi-
 mum voltage for which the apparatus is designed, and with non-induct-
 ive load, unless otherwise specified.

(F)—ROTARY INDUCTION APPARATUS, OR INDUCTION MACHINES.

- 162 In *Rotary Induction Apparatus*, the losses are:
 163 a. *Bearing Friction and Windage*. See Measurement of Losses (A),
 Sec. 102.
 164 b. *Molecular Magnetic Friction and Eddy Currents* in iron, copper
 and other metallic parts; also I^2r losses which may exist in multiple-
 circuit windings. a and b together are determined by running the
 motor without load at rated voltage, and measuring the power input.
 165 c. *Primary I^2R Loss*, which may be determined by measurement of
 the current and the resistance.
 166 d. *Secondary I^2R Loss*, which may be determined as in the primary,
 when feasible; otherwise, as in squirrel-cage secondaries, this loss is
 measured as part of e .
 167 e. *Load Losses*; i. e., molecular magnetic friction, and eddy currents
 in iron, copper, etc., caused by the stray field of primary and secondary
 currents, and secondary I^2R loss when undeterminable under (d). These
 losses may for practical purposes be determined by measuring the total
 power, with the rotor short-circuited at standstill and a current in the
 primary circuit equal to the primary energy current at full load. The
 loss in the motor under these conditions may be assumed to be equal to
 the load losses + I^2r losses in both primary and secondary coils.

(G)—UNIPOLAR OR ACYCLIC MACHINES.

168 In *Unipolar Machines*, the losses are:

169 (a) *Bearing Friction and Windage*. See Measurement of Losses (A), Sec. 102.

170 (b) *Molecular Magnetic Friction and Eddy Currents*. See Measurement of Losses (E), Sec. 106.

171 (c) *Armature Resistance Losses*. See Measurement of Losses (E), Sec. 110.

172 (d) *Collector Brush Friction*. See Measurement of Losses (C), Sec. 104.

173 (e) *Collector Brush Contact Resistance*. See Measurement of Losses (G), Sec. 112.

174 (f) *Field-Excitation* as in Sec. 113. See Measurement of Losses (H), Sec. 113.

175 (g) *Load Losses*. See Measurement of Losses (I), Sec. 114.

(H)—RECTIFYING APPARATUS, PULSATING-CURRENT GENERATORS.

176 *This Division Includes*: open-coil arc machines and mechanical and other rectifiers.

177 In *Rectifiers* the most satisfactory method of determining the efficiency is to measure both electric input and electric output by wattmeter. The input is usually inductive, owing to phase displacement and to wave distortion. For this reason the power factor and the apparent efficiency should also be considered, since the latter may be much lower than the true efficiency. The power consumed by auxiliary devices, such as the synchronous motor or cooling devices, should be included in the electric input.

178 In *Constant-Current Rectifiers*, transforming from constant potential alternating to constant direct current, by means of constant-current transforming devices and rectifying devices, the losses in the transforming devices are to be included in determining the efficiency and have to be measured when operating the rectifier, since in this case the losses may be greater than when feeding an alternating secondary circuit. In constant-current transforming devices, the load losses may be considerable, and, therefore, should not be neglected.

179 In *Open Coil Arc Machines*, the losses are essentially the same as in direct-current (closed coil) commutating machines. In this case, however, the load losses are usually greater, and the efficiency should preferably be measured by input- and output-test, using wattmeters for measuring the output. In alternating-current rectifiers, the output should, in general, be measured by wattmeter and not by voltmeter and ammeter, since owing to pulsation of current and voltage, a considerable discrepancy may exist between the watts and volt-amperes. If, however, a direct-current and an alternating-current meter in the rectified circuit (either a voltmeter or an ammeter) give the same reading, the output may be measured by direct-current voltmeter and ammeter. The type of alternating-current instrument here referred to should indicate the effective or root-of-mean-square value and the type of direct-current instrument the arithmetical mean value, which would be zero on an alternating-current circuit.

(I)—TRANSMISSION LINES.

180 The *Efficiency* of transmission lines should be measured with non-inductive load at the receiving end, with the rated receiving voltage and frequency, also with sinusoidal impressed wave form, except where expressly specified otherwise, and with the exclusion of transformers or other apparatus at the ends of the line.

(J)—PHASE-DISPLACING APPARATUS.

181 In *Apparatus Producing Phase Displacement* as, for example, synchronous compensators, exciters of induction generators, reactors, condensers, polarization cells, etc., the efficiency should be understood to be the ratio of the volt-amperes minus power loss to the volt-amperes.

182 The *Efficiency* may be calculated by determining the losses, subtracting them from the volt-amperes, and then dividing the difference by the volt-amperes.

183 In *Synchronous Compensators* and exciters of induction generators, the determination of losses is the same as in other synchronous machines.

- 184 In *Reactors* the losses are molecular magnetic friction, eddy losses and I^2R loss. They should be measured by wattmeter. The efficiency of reactors should be determined with a sine wave of impressed voltage except where expressly specified otherwise.
- 185 In *Condensers*, the losses are due to dielectric hysteresis and leakage, and should be determined by wattmeter with a sine wave of voltage.
- 186 In *Polarisation Cells*, the losses are those due to electric resistivity and a loss in the electrolyte of the nature of chemical hysteresis. These losses may be considerable. They depend upon the frequency, voltage and temperature, and should be determined with a sine wave of impressed voltage, except where expressly specified otherwise.

D.—REGULATION.

(I)—DEFINITIONS.

- 187 *Definition.* The regulation of a machine or apparatus in regard to some characteristic quantity (such as terminal voltage, current or speed) is the ratio of the deviation of that quantity from its normal value at rated load to the normal rated load value. The term "regulation," therefore, has the same meaning as the term "inherent regulation," occasionally used.
- 188 *Constant Standard.* If the characteristic quantity is intended to remain constant (e. g., constant voltage, constant speed, etc.) between rated load and no load, the regulation is the ratio of the maximum variation from the rated-load value to the no-load value.
- 189 *Varying Standard.* If the characteristic quantity is intended to vary in a definite manner between rated load and no load, the regulation is the ratio of the maximum variation from the specified condition to the normal rated-load value.
- 190 (a) Note.—If the law of the variation (in voltage, current, speed, etc.) between rated-load and no-load is not specified, it should be assumed to be a simple linear relation; i. e., one undergoing uniform variation between rated-load and no-load.
- 191 (b) Note.—The regulation of an apparatus may, therefore, differ according to its qualification for use. Thus, the regulation of a compound-wound generator specified as a constant-potential generator, will be different from that which it possesses when specified as an over-compounded generator.
- 192 In *Constant-Potential Machines*, the regulation is the ratio of the maximum difference of terminal voltage from the rated-load value (occurring within the range of rated load to open circuit) to the rated-load terminal voltage.
- 193 In *Constant-Current Machines*, the regulation is the ratio of the maximum difference of current from the rated-load value (occurring within the range from rated-load to short-circuit, or minimum limit of operation), to the rated-load current.
- 194 In *Constant-Power Apparatus*, the regulation is the ratio of maximum difference of power from the rated-load value (occurring within the range of operation specified) to the rated power.
- 195 In *Constant-Speed Direct-Current Motors and Induction Motors* the regulation is the ratio of the maximum variation of speed from its rated-load value (occurring within the range from rated-load to no-load) to the rated-load speed.
- 196 The regulation of an induction motor is, therefore, not identical with the slip of the motor, which is the ratio of the drop in speed from synchronism, to the synchronous speed.
- 197 In *Constant-Potential Transformers*, the regulation is the ratio of the rise of secondary terminal voltage from rated non-inductive load to no-load (at constant primary impressed terminal voltage) to the secondary terminal voltage at rated load.
- 198 In *Over-Compounded Machines*, the regulation is the ratio of the maximum difference in voltage from a straight line connecting the no-load and rated-load values of terminal voltage as function of the load current, to the rated-load terminal voltage.
- 199 In *Converters, Dynamotors, Motor-Generators and Frequency Converters*, the regulation is the ratio of the maximum difference of terminal voltage at the output side from the rated-load voltage, to the rated-load voltage on the output side.
- 200 In *Transmission Lines, Feeders, etc.*, the regulation is the ratio of

the maximum voltage difference at the receiving end, between rated non-inductive load and no-load to the rated-load voltage at the receiving end (with constant voltage impressed upon the sending end).

- 201 In *Steam Engines*, the regulation is the ratio of the maximum variation of speed in passing slowly from rated-load to no-load (with constant steam pressure at the throttle) to the rated-load speed. For variation and pulsation, see Secs. 59-64.
- 202 In a *Hydraulic Turbine or Other Water-Motor*, the regulation is the ratio of the maximum variation of speed in passing slowly from rated-load to no-load (at constant head of water; i. e., at constant difference of level between tail race and head race), to the rated-load speed. For variation and pulsation, see Secs. 59-64.
- 203 In a *Generator-Unit*, consisting of a generator united with a prime-mover, the regulation should be determined at constant conditions of the prime-mover; i. e., constant steam pressure, head, etc. It includes the inherent speed variations of the prime-mover. For this reason the regulation of a generator-unit is to be distinguished from the regulation of either the prime-mover, or of the generator contained in it, when taken separately.

(II)—CONDITIONS FOR AND TESTS OF REGULATION.

- 204 *Speed.* The *Regulation of Generators* is to be determined at constant speed, and of alternating apparatus at constant impressed frequency.
- 205 *Non-Inductive Load.* In apparatus generating, transforming or transmitting alternating currents, regulation should be understood to refer to non-inductive load, that is, to a load in which the current is in phase with the e.m.f. at the output side of the apparatus, except where expressly specified otherwise.
- 206 *Wave Form.* In alternating apparatus receiving electric power, regulation should refer to a sine wave of e.m.f., except where expressly specified otherwise.
- 207 *Excitation.* In commutating machines, rectifying machines, and synchronous machines, such as direct-current generators and motors, alternating-current and polyphase generators, the regulation is to be determined under the following conditions:
- (1) At constant excitation in separately excited fields.
 - (2) With constant resistance in shunt-field circuits, and
 - (3) With constant resistance shunting series-field circuits; i. e., the field adjustment should remain constant, and should be so chosen as to give the required full-load voltage at full-load current.
- 208 *Impedance Ratio.* In alternating-current apparatus, in addition to the non-inductive regulation, the impedance ratio of the apparatus should be specified; i. e., the ratio of the voltage consumed by the total internal impedance of the apparatus at full-load current, to its rated full-load voltage. As far as possible, a sinusoidal current should be used.
- 209 *Computation of Regulation.* When in synchronous machines the regulation is computed from the terminal voltage and impedance voltage, the exciting ampere-turns corresponding to terminal voltage plus armature-resistance-drop, and the ampere-turns at short-circuit corresponding to the armature-impedance-drop, should be combined vectorially to obtain the resultant ampere-turns, and the corresponding internal e. m. f. should be taken from the saturation curve.

E.—INSULATION.

(I)—INSULATION RESISTANCE.

- 210 *Insulation Resistance* is the ohmic resistance offered by an insulating coating, cover, material or support to an impressed voltage, tending to produce a leakage of current through the same.
- 211 *Ohmic Resistance and Dielectric Strength.* The ohmic resistance of the insulation is of secondary importance only, as compared with the dielectric strength, or resistance to rupture by high voltage. Since the ohmic resistance of the insulation can be very greatly increased by baking, but the dielectric strength is liable to be weakened thereby, it is preferable to specify a high dielectric strength rather than a high insulation resistance. The high-voltage test for dielectric strength should always be applied.

- 212 *Recommended Value of Resistance.* The insulation resistance of complete apparatus should be such that ¹the rated voltage of the apparatus which will not send more than $\frac{1}{1,000,000}$ of the rated-load current, at the rated terminal voltage, through the insulation. Where the value found in this way exceeds 1 megohm, it is usually sufficient.
- 213 *Insulation Resistance Tests* should, if possible, be made at the pressure for which the apparatus is designed.

(II)—DIELECTRIC STRENGTH.

(A)—TEST VOLTAGES.

- 214 *Definition.* The dielectric strength of an insulating wall, coating cover or path is measured by the voltage which must be applied to it in order to effect a disruptive discharge through the same.
- 215 *Basis for Determining Test Voltages.* The test voltage which should be applied to determine the suitability of insulation for commercial operation is dependent upon the kind and size of the apparatus and its normal operating voltage, upon the nature of the service in which it is to be used, and the severity of the mechanical and electrical stresses to which it may be subjected. The voltages and other conditions of test which are recommended have been determined as reasonable and proper for the great majority of cases and are proposed for general adoption, except when specific reasons make a modification desirable.
- 216 *Condition of Apparatus to be Tested.* Commercial tests should, in general, be made with the completely assembled apparatus and not with individual parts. The apparatus should be in good condition and high-voltage tests, unless otherwise specified, should be applied before the machine is put into commercial service, and should not be applied when the insulation resistance is low owing to dirt or moisture. High-voltage tests should, in general, be made at the temperature assumed under normal operation. High-voltage tests considerably in excess of the normal voltages to determine whether specifications are fulfilled are admissible on new machines only.
- 217 *Points of Application of Voltage.* The test voltage should be successively applied between each electric circuit and all other electric circuits including conducting material in the apparatus.
- 218 *The Frequency of the alternating-current test voltage* is, in general, immaterial within commercial ranges. When, however, the frequency has an appreciable effect, as in alternating-current apparatus of high voltage and considerable capacity, the rated frequency of the apparatus should be used.
- 219 *Table of Testing Voltages.* The following voltages are recommended for testing all apparatus, lines and cables, by a continued application for one minute. The test should be with alternating voltage having an effective value (or root mean square referred to a sine wave of voltage) given in the table and preferably for tests of alternating apparatus at the normal frequency of the apparatus.

	Rated Terminal Voltage of Circuit.	Rated Output.	Testing Voltage.
220	Not exceeding 400 volts.....	Under 10 kw.....	1,000 volts.
	400 " " " " " " " " " " " "	10 kw. and over....	1,500 "
	400 and over, but less than 800 volts.....	Under 10 kw.....	1,500 "
	400 " " " " " " " " " " " "	10 kw. and over....	2,000 "
	800 " " " " " " " " " " " "	Any.....	3,500 "
	1,200 " " " " " " " " " " " "	Any.....	5,000 "
	2,500 " " " " " " " " " " " "	Any.. Double the normal rated	Voltages.

- 221 *Exception.—Transformers.* Transformers having primary pressures of from 550 to 5,000 volts, the secondaries of which are directly connected to consumption circuits, should have a testing voltage of 10,000 volts, to be applied between the primary and secondary windings, and also between the primary winding and the core.
- 222 *Exception.—Field Windings.* The tests for field windings should be based on the rated voltage of the exciter and the rated output of the machine of which the coils are a part. Field windings of synchronous motors and converters, which are to be started by applying alternating

current to the armature when the field is not excited and a high voltage is induced in the field windings, should be tested at 5,000 volts.

- 223** *Rated Terminal Voltage.—Definition.* The rated terminal voltage of circuit in the above table, means the voltage between the conductors of the circuit to which the apparatus to be tested is to be connected,—for instance, in three-phase circuits the delta voltage should be taken. In the following specific cases, the rated terminal voltage of the circuit is to be determined as specified in ascertaining the testing voltage:
- 224** (a) *Transformers.* The test of the insulation between the primary and secondary windings of transformers, is to be the same as that between the high-voltage windings and core, and both tests should be made simultaneously by connecting the low-tension winding and core together during the test. If a voltage equal to the specified testing voltage be induced in the high-tension winding of a transformer it may be used for insulation tests instead of an independently induced voltage. These tests should be made first with one end and then with the other end of the high-tension winding connected to the low-tension winding and to the core.
- 225** (b) *Constant-Current Apparatus.* The testing voltage is to be based upon a rated terminal voltage equal to the maximum voltage which may exist at open or closed circuit.
- 226** (c) *Apparatus in Series.* For tests of machines or apparatus to be operated in series, so as to employ the sum of their separate voltages the testing voltage is to be based upon a rated terminal voltage equal to the sum of the separate voltages except where the frames of the machines are separately insulated, both from the ground and from each other, in which case the test for insulation between machines should be based upon the voltage of one machine, and the test between each machine and ground to be based upon the total voltage of the series

(B)—METHODS OF TESTING.

- 227** *Classes of Tests.* Tests for dielectric strength cover such a wide range in voltage that the apparatus, methods and precautions which are essential in certain cases do not apply to others. For convenience, the tests will be separated into two classes:
- 228** *Class 1.* This class includes all apparatus for which the test voltage does not exceed 10 kilovolts, unless the apparatus is of very large static capacity, e. g., a large cable system. This class also includes all apparatus of small static capacity, such as line insulators, switches and the like, for all test voltages.
- 229** *Method of Test for Class 1.* The test voltage is to be continuously applied for the prescribed interval,—(one minute, unless otherwise specified). The test voltage may be taken from a constant-potential source and applied directly to the apparatus to be tested, or it may be raised gradually as specified for tests under Class 2.
- 230** *Class 2.* This class includes all apparatus not included in Class 1.
- 231** *Method of Test for Class 2.* The test voltage is to be raised to the required value smoothly and without sudden large increments and is then to be continuously applied for the prescribed interval,—(one minute, unless otherwise specified), and then gradually decreased.
- 232** *Conditions and Precautions for Class 1 and Class 2.* The following apply to all tests:
- 233** The *Wave Shape* should be approximately sinusoidal and the apparatus in the testing circuits should not materially distort this wave.
- 234** The *Supply Circuit* should have ample current-supply capacity so that the charging current which may be taken by the apparatus under test will not materially alter the wave form nor materially affect the test voltage. The circuit should be free from accidental interruptions.
- 235** *Resistance or Inductance* in series with the primary of a raising transformer for the purpose of controlling its voltage is liable seriously to affect the wave form, thereby causing the maximum value of the voltage to bear a different and unknown ratio to the root mean square value. This method of voltage adjustment is, therefore, in general, undesirable. It may be noted that if a resistance or inductance is employed to limit the current when burning out a fault, such resistance or inductance should be short-circuited during the regular voltage test.
- 236** The *Insulation* under test should be in normal condition as to dryness and the temperature should, when possible, be that reached in normal service.

237 *Additional Conditions and Precautions for Class 2.* The following conditions and precautions, in addition to the foregoing, apply to tests of apparatus included in Class 2.

238 *Sudden Increment of Testing Voltage* on the apparatus under test should be avoided, particularly at high voltages and with apparatus having considerable capacity, as a momentarily excessive rise in testing voltage will result.

239 *Sudden Variations in Testing Voltage* of the circuit supplying the voltage during the test should be avoided as they are likely to set up injurious oscillation.

240 *Good Connections* in the circuits supplying the test voltage are essential in order to prevent injurious high frequency disturbances from being set up. When a heavy current is carried by a small water rheostat, arcing may occur, causing high-frequency disturbances which should be carefully avoided.

241 *Transformer Coils.* In high-tension transformers, the low-tension coil should preferably be connected to the core and the ground when the high-tension test is being made, in order to avoid the stress from low-tension to core, which would otherwise result through condenser action. The various terminals of each winding of the high-tension transformer under test should be connected together during the test in order to prevent undue stress on the insulation between turns or sections of the winding in case the high-voltage test causes a breakdown.

(C)—METHODS FOR MEASURING THE TEST VOLTAGE.

242 *For Measuring the Test Voltage*, two instruments are in common use, (1) the spark gap, and (2) the voltmeter.

243 1. *The Spark Gap* is ordinarily adjusted so that it will break down with a certain predetermined voltage, and is connected in parallel with the insulation under test. It ensures that the voltage applied to the insulation is not greater than the break-down voltage of the spark gap. A given setting of the spark gap is a measure of one definite voltage, and, as its operation depends upon the maximum value of the voltage wave, it is independent of wave form and is a limit on the maximum stress to which the insulation is subjected. The spark gap is not conveniently adapted for comparatively low voltages.

244 In *Spark-Gap Measurements*, the spark gap may be set for the required voltage and the auxiliary apparatus adjusted to give a voltage at which this spark gap just breaks down. This spark gap should then be adjusted for, say, 10 per cent higher voltage, and the auxiliary apparatus again adjusted to give the voltage of the former breakdown, which is to be the assumed voltage for the test. This voltage is to be maintained for the required interval.

245 The *Spark Points* should consist of new sewing needles, supported axially at the ends of linear conductors which are each at least twice the length of the gap. There should be no extraneous body near the gap within a radius of twice its length. A table of approximate striking distances is given in Appendix D. This table should be used in connection with tests made by the spark-gap methods.

246 A *Non-Inductive Resistance* of about one-half ohm per volt should be inserted in series with each terminal of the gap so as to keep the discharge current between the limits of one-quarter ampere and 2 amperes. The purpose of the resistance is to limit the current in order to prevent the surges which might otherwise occur at the time of break-down.

247 2. *The Voltmeter* gives a direct reading, and the different values of the voltage can be read during the application and duration of the test. It is suitable for all voltages, and does not introduce disturbances into the test circuit.

248 In *Voltmeter Measurements*, the voltmeter should, in general, derive its voltage from the high-tension testing circuit either directly or through an auxiliary ratio transformer. It is permissible, however, to measure the voltage at other places,—for example, on the primary of the transformer, provided the ratio of transformation does not materially vary during the test; or that proper account is taken thereof.

249 *Spark Gap and Voltmeter.* The spark gap may be employed as a check upon the voltmeter used in high-tension tests in order to determine the transformation ratio of the transformer, the variation from the sine wave form and the like. It is also useful in conjunction with

voltmeter measurements to limit the stress applied to the insulating material.

(D)—APPARATUS FOR SUPPLYING TEST VOLTAGE.

- 250 The *Generator or Circuit* supplying voltage for the test should have ample current-carrying capacity, so that the current which may be taken for charging the apparatus to be tested will not materially alter the wave form nor otherwise materially change the voltage.

The *Testing Transformer* should be such that its ratio of transformation does not vary more than 10 per cent when delivering the charging current required by the apparatus under test. (This may be determined by short-circuiting the secondary or high voltage winding testing transformer and supplying 1/10 of the primary voltage to the primary under this condition. The primary current that flows under this condition is the maximum which should be permitted in regular dielectric tests.)

- 251 The *Voltage Control* may be secured in either of several ways, which, in order of preference, are as follows:

- 252 1. By generator field circuit.
253 2. By magnetic commutation.
254 3. By change in transformer ratio.
255 4. By resistance or choke coils.

- 256 In *Generator Voltage Control*, the voltage of the generator should preferably be about its approximate normal rated-load value when the full testing voltage is attained, which requires that the ratio of the raising transformer be such that the full testing voltage is reached when the generator voltage is normal. This avoids the instability in the generator which may occur if a considerable leading current is taken from it when it has low voltage and low field current.

- 257 In *Magnetic Commutation*, the control is effected by shunting the magnetic flux through a secondary coil so as to vary the induction through the coil and the voltage induced in it. The shunting should be effected smoothly, thus avoiding sudden changes in the induced voltage.

- 258 In *Transformer Voltage Control*, by change of ratio, it is necessary that the transition from one step to another be made without interruption of the test voltage, and by steps sufficiently small to prevent surges in the testing circuit. The necessity of this precaution is greater as the inductance or the static capacity of the apparatus in the testing circuit under test is greater.

- 259 When *Resistance Coils or Reactors* are used for voltage control, it is desirable that the testing voltage should be secured when the controlling resistance or reactance is very nearly or entirely out of circuit in order that the disturbing effect upon the wave form which results may be negligible at the highest voltage.

F.—CONDUCTIVITY.

- 260 *Copper*. The conductivity of copper in electric wires and cables should not be less than 98% of Matthiessen's standard of conductivity, as defined in the Copper Wire Table of the *American Institute of Electrical Engineers*. [See Table I, page 1388.]

G.—RISE OF TEMPERATURE.

(I)—MEASUREMENT OF TEMPERATURE.

(A)—METHODS.

- 261 There are two methods in common use for determining the rise in temperature, viz.: (1) by thermometer, and (2) by increase in resistance of an electric circuit.

- 262 1. By *Thermometer*. The following precautions should be observed in the use of thermometers:

- 263 a. *Protection*. The thermometers indicating the room temperature should be protected from thermal radiation emitted by heated bodies, or from draughts of air or from temporary fluctuations of temperature. Several room thermometers should be used. In using the thermometer by applying it to a heated part, care should be taken so to protect its bulb as to prevent radiation from it, and, at the same time, not to interfere seriously with the normal radiation from the part to which it is applied.

264 *b. Bulb.* When a thermometer is applied to the free surface of a machine, it is desirable that the bulb of the thermometer should be covered by a pad of definite area. A convenient pad may be formed of cotton waste in a shallow circular box about one and a half inches in diameter, through a slot in the side in which the thermometer bulb is inserted. An unduly large pad over the thermometer tends to interfere with the natural liberation of heat from the surface to which the thermometer is applied.

265 2. *By Increase in Resistance.* The resistance may be measured either by Wheatstone bridge, or by drop-of potential method. A temperature coefficient of 0.42 per cent per degree C., from and at 0°C., may be assumed for copper.

The temperature-coefficients from and at each degree cent. between 0°C. and 50°C. are given in Appendix E. The temperature rise may be determined either (1) by dividing the percentage increase of initial resistance by the temperature-coefficient for the initial temperature expressed in per cent; or (2) by multiplying the increase in per cent of the initial resistance by 238.1 plus the initial temperature in degrees C., and then dividing the product by 100.

266 3. *Comparison of Methods.* In electrical conductors, the rise of temperature should be determined by their increase of resistance where practicable. Temperature elevations measured in this way are usually in excess of temperature elevations measured by thermometers. In very low resistance circuits, thermometer measurements are frequently more reliable than measurements by the resistance method. Where a thermometer applied to a coil or winding, indicates a higher temperature elevation than that shown by resistance measurement, the thermometer indication should be accepted.

(B)—NORMAL CONDITIONS FOR TESTS.

267 1. *Duration of Tests.* The temperature should be measured after a run of sufficient duration for the apparatus to reach a practically constant temperature. This is usually from 6 to 18 hours, according to the size and construction of the apparatus. It is permissible, however, to shorten the time of the test by running a lesser time on an overload in current and voltage, then reducing the load to normal, and maintaining it thus until the temperature has become constant.

268 2. *Room Temperature.* The rise of temperature should be referred to the standard condition of a room temperature of 25°C.

269 *Temperature Correction.* If the room temperature during the test differs from 25°C., correction on account of difference in resistance should be made by changing the observed rise of temperature by one-half per cent for each degree C. Thus with a room temperature of 35°C., the observed rise of temperature has to be decreased by 5 per cent, and with a room temperature of 15°C., the observed rise of temperature has to be increased by 5 per cent. In certain cases, such as shunt-field circuit without rheostat, the current strength will be changed by a change of room temperature. The heat-production and dissipation may be thereby affected. Correction for this should be made by changing the observed rise in temperature in proportion as the I^2R loss in the resistance of the apparatus is altered owing to the difference in room temperature.

270 3. *Barometric Pressure. Ventilation.* A barometric pressure of 760 mm. and normal conditions of ventilation should be considered as standard, and the apparatus under test should neither be exposed to draught nor enclosed, except where expressly specified. The barometric pressure needs to be considered only when differing greatly from 760 mm.

271 *Barometric Pressure Correction.* When the barometric pressure differs greatly from the standard pressure of 760 mm. of mercury, as at high altitudes, a correction should be applied. In the absence of more accurate data, a correction of 1% of the observed rise in temperature for each 10 mm. deviation from the 760 mm. standard is recommended. For example, at a barometric pressure of 680 mm. the observed rise of

temperature is to be reduced by $\frac{760 - 680}{10} = 8\%$.

(II)—LIMITING TEMPERATURE RISE.

- 272 *General.* The temperature of electrical machinery under regular service conditions, should never be allowed to remain at a point at which permanent deterioration of its insulating material takes place
- 273 *Limits Recommended.* It is recommended that the following maximum values of temperature elevation, referred to a standard room temperature of 25° centigrade, at rated load under normal conditions of ventilation or cooling, should not be exceeded.

(A)—MACHINES IN GENERAL.

- 274 In commutating machines, rectifying machines, pulsating-current generators, synchronous machines, synchronous commutating machines and unipolar machines, the temperature rise in the parts specified should not exceed the following:
- 275 Field and armature, 50°C.
- 276 Commutator and brushes, by thermometer, 55°C.
- 277 Collector rings, 65°C.
- 278 Bearings and other parts of machine, by thermometer, 40°C.

(B)—ROTARY INDUCTION APPARATUS.

- 279 The temperature rise should not exceed the following:
- 280 Electric circuit, 50°C., by resistance.
- 281 Bearings and other parts of the machine 40°C., by thermometer.
- 282 In squirrel-cage or short-circuited armatures, 55°C., by thermometer, may be allowed.

(C)—STATIONARY INDUCTION APPARATUS.

- 283 *a. Transformers for Continuous Service.* The temperature rise should not exceed 50° centigrade in electric circuits, by resistance; and in other parts, by thermometer.
- 284 *b. Transformers for Intermittent Service.* In the case of transformers intended for intermittent service, or not operations continuously at rated load, but continuously in circuit, as in the ordinary case of lighting transformers, the temperature elevation above the surrounding air-temperature should not exceed 50°C., by resistance in electric circuits and by thermometer in other parts, after the period corresponding to the term of rated load. In this instance, the test load should not be applied until the transformer has been in circuit for a sufficient time to attain the temperature elevation due to core loss. With transformers for commercial lighting, the duration of the rated-load test may be taken as three hours, unless otherwise specified.
- 285 *c. Reactors,* induction- and magneto-regulators—electric circuits by resistance and other parts by thermometer, 50°C.
- 286 *a. Large Apparatus.* Large generators, motors, transformers, or other apparatus in which reliability and reserve overload capacity are important, are frequently specified not to rise in temperature more than 40° centigrade under rated load and 55° centigrade at rated overload. It is, however, ordinarily undesirable to specify lower temperature elevations than 40° centigrade at rated load, measured as above.

(D)—RHEOSTATS.

- 287 In *Rheostats, Heaters* and other electrothermal apparatus, no combustible or inflammable part or material, or portion liable to come in contact with such material, should rise more than 50°C. above the surrounding air under the service conditions for which it is designed.
- 288 *a. Parts of Rheostats.* Parts of rheostats and similar apparatus rising in temperature, under the specified service conditions, more than 50°C., should not contain any combustible material, and should be arranged or installed in such a manner that neither they, nor the hot air issuing from them, can come in contact with combustible material.

(E)—LIMITS RECOMMENDED IN SPECIAL CASES.

- 289 *a. Heat Resisting Insulation.* With apparatus in which the insulating materials have special heat-resisting qualities, a higher temperature elevation is permissible.
- 290 *b. High Air Temperature.* In apparatus intended for service in places of abnormally high temperature, a lower temperature elevation should be specified.

- 291 *c. Apparatus Subject to Overload.* In apparatus which by the nature of its service may be exposed to overload, or is to be used in very high voltage circuits, a smaller rise of temperature is desirable than in apparatus not liable to overloads or in low-voltage apparatus. In apparatus built for conditions of limited space, as railway motors, a higher rise of temperature must be allowed.
- 292 *d. Apparatus for Intermittent Service.* In the case of apparatus intended for intermittent service, except railway motors, the temperature elevation which is attained at the end of the period corresponding to the term of rated load, should not exceed the values specified for machines in general. In such apparatus the temperature elevation, including railway motors, should be measured after operation, under as nearly as possible the conditions of service for which the apparatus is intended, and the conditions of the test should be specified.

H.—OVERLOAD CAPACITIES.

- 293 *Performance with Overload.* All apparatus should be able to carry the overload hereinafter specified without serious injury by heating, sparking, mechanical weakness, etc., and with an additional temperature rise not exceeding $15^{\circ}\text{C}.$, above those specified for rated loads, the overload being applied after the apparatus has acquired the temperature corresponding to rated load continuous operation. Rheostats to which no temperature rise limits are attached are naturally exempt from this additional temperature rise of $15^{\circ}\text{C}.$ under overload specified in these rules.
- 294 *Normal Conditions.* Overload guarantees should refer to normal conditions of operation regarding speed, frequency, voltage, etc., and to non-inductive conditions in alternating apparatus, except where a phase displacement is inherent in the apparatus.
- 295 *Overload Capacities Recommended.* The following overload capacities are recommended:
- 296 *a. Generators.* Direct-current generators and alternating-current generators, 25 per cent for two hours.
- 297 *b. Motors.* Direct-current motors, induction motors and synchronous motors, not including railway and other motors intended for intermittent service, 25 per cent for two hours, and 50 per cent for one minute.
- 298 *c. Converters.* Synchronous converters, 25 per cent for two hours, 50 per cent for one-half hour.
- 299 *d. Transformers and Rectifiers.* Constant-potential transformers and rectifiers, 25 per cent for two hours; except in transformers connected to apparatus for which a different overload is guaranteed, in which case the same guarantees shall apply for the transformers as for the apparatus connected thereto.
- 300 *e. Exciters.* Exciters of alternators and other synchronous machines, 10 per cent more overload than is required for the excitation of the synchronous machine at its guaranteed overload, and for the same period of time. All exciters of alternating-current, single-phase or polyphase generators should be able to give at its rated speed, sufficient voltage and current to excite the alternator, at the rated speed, to the full-load terminal voltage, at the rated output in kilovolt-amperes and with 50 per cent power factor.
- 301 *f. A Continuous-Service Rheostat,* such as an armature- or field-regulating rheostat, should be capable of carrying without injury for two hours, a current 25 per cent greater than that at which it is rated. It should also be capable of carrying for one minute a current 50 per cent greater than its rated load current, without injury. This excess of capacity is intended for testing purposes only, and this margin of capacity should not be relied upon in the selection of the rheostat.
- 302 *g. An Intermittent Service or Motor-Starting Rheostat* is used for starting a motor from rest and accelerating it to rated speed. Under ordinary conditions of service, and unless expressly stated otherwise, a motor is assumed to start in fifteen seconds and with 150% of rated current strength. A motor-starter should be capable of starting the motor under these conditions once every four minutes for one hour.
- 303 *(a) This Test* may be carried out either by starting the motor at four-minute intervals, or by placing the starter at normal temperature across the maximum voltage for which it is marked, and moving the lever uniformly and gradually from the first to the last position during a

period of fifteen seconds, the current being maintained substantially constant at said 50% excess by introducing resistance in series or by other suitable means.

- 304 (b) *Other Rheostats for Intermittent-Service* are employed under such special and varied conditions, that no general rules are applicable to them.

III.—VOLTAGES AND FREQUENCIES.

A.—VOLTAGES.

- 305 *Direct-Current Generators.* In direct-current, low-voltage generators, the following average terminal voltages are in general use and are recommended:
- | | | |
|------------|------------|-------------------|
| 125 volts. | 250 volts. | 550 to 600 volts. |
|------------|------------|-------------------|
- 306 *Low-Voltage Circuits.* In direct-current and alternating-current low-voltage circuits, the following average terminal voltages are in general use and are recommended:
- | | |
|------------|------------|
| 110 volts. | 220 volts. |
|------------|------------|
- 307 *Primary Distribution Circuits.* In alternating-current, constant-potential, primary-distribution circuits, an average voltage of 2,200 volts, with step-down transformer ratios 1/10 and 1/20, is in general use, and is recommended.
- 308 *Transmission Circuits.* In alternating-current constant-potential transmission circuits, the following average voltages are recommended.
- | | | | | | | |
|-------|--------|--------|--------|--------|--------|--------|
| 6,600 | 11,000 | 22,000 | 33,000 | 44,000 | 66,000 | 88,000 |
|-------|--------|--------|--------|--------|--------|--------|
- 309 *Transformer Ratio.* It is recommended that the standard transformer ratios should be such as to transform between the standard voltages above named. The ratio will, therefore, usually be an exact multiple of 5 or 10, e. g., 2,200 to 11,000; 2,200 to 44,000.
- 310 *Range in Voltage.* In alternating-current generators, or generating systems, a range of terminal voltage should be provided from rated voltage at no load to 10 per cent in excess thereof, to cover drop in transmission. If a greater range than ten per cent is specified, the generator should be considered as special.

B.—FREQUENCIES.

- 311 In *Alternating-Current Circuits*, the following frequencies are standard:
- | | |
|-----|-----|
| 25~ | 60~ |
|-----|-----|
- 312 These frequencies are already in extensive use and it is deemed advisable to adhere to them as closely as possible.

IV.—GENERAL RECOMMENDATIONS.

- 313 *Name Plates.* All electrical apparatus should be provided with a name plate giving the manufacturer's name, the voltage and the current in amperes for which it is designed. Where practicable, the kilowatt capacity, character of current, speed, frequency, type, designation and serial number should be added.
- 314 *Diagrams of Connections.* All electrical apparatus when leaving the factory should be accompanied by a diagram showing the electrical connections and the relation of the different parts in sufficient detail to give the necessary information for proper installation.
- 315 *Rheostat Data.* Every rheostat should be clearly and permanently marked with the voltage and amperes, or range of amperes, for which it is designed.
- 316 *Colored Indicating Lights.* When using colored indicating lights on switch-boards, red should denote danger such as "switch closed," or "circuit alive;" green should denote safety, such as "switch open," or "circuit dead."
- 317 When white lights are used a light turned on should denote danger, such as "switch closed" or "circuit alive;" while the light out should denote safety, such as "switch open," or "circuit dead." Low-efficiency lamps should be used.
- 318 The use of colored lights is recommended, as safer than white lights.

- 319** *Grounding Metal Work.* It is desirable that all metal work near high potential circuits be grounded.
- 320** *Circuit Opening Devices.* The following definitions are recommended.
- 321** *a. A Circuit-Breaker* is an apparatus for breaking a circuit at the highest current which it may be called upon to carry.
- 322** *b. A Disconnecting Switch* is an apparatus designed to open a circuit only when carrying little or no current.
- 323** *c. An Automatic Circuit-Breaker* is an apparatus for breaking a circuit automatically under an excessive strength of current. It should be capable of breaking the circuit repeatedly at rated voltage and at the maximum current which it may be called upon to carry.

V.—APPENDICES AND TABULAR DATA.

APPENDIX A.—NOTATION.

- 324** The following notation is recommended:
- E, e*, voltage, e.m.f., potential difference
- I, i*, current
- P*, power
- Φ , magnetic flux
- B, B*, magnetic density
- R, r*, resistance
- x*, reactance
- Z, z*, impedance
- L, l*, inductance
- C, c*, capacity
- Y, y*, admittance
- b*, susceptance
- G, g*, conductance
- Vector quantities when used should be denoted by capital italics.

APPENDIX B.—RAILWAY MOTORS.

(I)—RATING.

- 325** *Introductory Note on Rating.* Railway motors usually operate in a service in which both the speed and the torque developed by the motor are varying almost continually. The average requirements, however, during successive hours in a given class of service are fairly uniform. On account of the wide variation of the instantaneous loads, it is impracticable to assign any simple and definite rating to a motor which will indicate accurately the absolute capacity of a given motor or the relative capacity of different motors under service conditions. It is also impracticable to select a motor for a particular service without much fuller data with regard both to the motor and to the service than is required, for example, in the case of stationary motors which run at constant speeds.
- 326** *Scope of Nominal Rating.* It is common usage to give railway motors a nominal rating in horse power on the basis of a one-hour test. As above explained, a simple rating of this kind is not a proper measure of service capacity. The nominal rating, however, indicates approximately the maximum output which the motor should ordinarily be called upon to develop during acceleration. Methods of determining the continuous capacity of a railway motor for service requirements are given under a subsequent heading.
- 327** *The Nominal Rating* of a railway motor is the horse-power output at the car-axle, that is, including gear and other transmission losses, which gives a rise of temperature above the surrounding air (referred to a room temperature of 25° Cent.) not exceeding 90° Cent. at the commutator and 75° Cent. at any other part after one hour's continuous run at its rated voltage (and frequency, in the case of an alternating-current motor) on a stand, with the motor-covers removed, and with natural ventilation. The rise in temperature is to be determined by thermometer, but the resistance of no electrical circuit in the motor shall increase more than 40% during the test.

(II)—SELECTION OF MOTOR FOR SPECIFIED SERVICE.

- 328 *General Requirements.* The suitability of a railway motor for a specified service depends upon the following considerations:
- 329 a. Mechanical ability to develop the requisite torque and speeds as given by its speed-torque curve.
- 330 b. Ability to commutate successfully the current demanded.
- 331 c. Ability to operate in service without occasioning a temperature rise in any part which will endanger the life of the insulation.
- 332 *Operating Conditions, Typical Run.* The operating conditions which are important in the selection of a motor include the weight of load, the schedule speed, the distance between stops, the duration of stops, the rate of acceleration and of breaking retardation, the grades and the curves. With these data at hand, the outputs which are required of the motor may be determined, provided the service requirements are within the limits of the speed-torque curve of the motor. These outputs may be expressed in the form of curves giving the instantaneous values of current and of voltage which must be applied to the motor. Such curves may be laid out for the entire line, but they are usually constructed only for a certain average or typical run, which is fairly representative of the conditions of service. To determine whether the motor has sufficient capacity to perform the service safely, further tests or investigations must be made.
- 333 *Capacity Test of Railway Motor in Service.* The capacity of a railway motor to deliver the necessary output may be determined by measurement of its temperature after it has reached a maximum in service. If a running test cannot be made under the actual conditions of service, an equivalent test may be made in a typical run back and forth, under such conditions of schedule speed, length of run, rate of acceleration, etc., that the test cycle of motor losses and conditions of ventilation are essentially the same as would be obtained in the specified service.
- 334 *Methods of Comparing Motor Capacity with Service Requirements.* Where it is not convenient to test motors under actual service conditions or in an equivalent typical run, recourse may be had to one of the two following methods of determining temperature rise now in general use:
- 335 1. *Method by Losses and Thermal Capacity Curves.* The heat developed in a railway motor is carried partly by conduction through the several parts and partly by convection through the air to the motor-frame whence it is distributed to the outside air. As the temperature of the several parts is thus dependent not only upon their own internal losses but also upon the temperature of neighboring parts, it becomes necessary to determine accurately the actual value and distribution of losses in a railway motor for a given service and reproduce them in an equivalent test-run. The results of a series of typical runs expressed in the form of thermal capacity curves will give the relation between degrees rise per watt loss in the armature and in the field for all ratios of losses between them met with in the commercial application of a given motor.
- 336 This method consists, therefore, in calculating the several internal motor losses in a specified service and determining the temperature rise with these losses from thermal capacity curves giving the degrees rise per watt loss as obtained in experimental track tests made under the same conditions of ventilation.
- 337 The following motor losses cause its heating and should be carefully determined for a given service: I^2R in the field; I^2R in the armature; I^2R in the brush contacts, core loss and brush friction.
- 338 The loss in the bearings (in the case of geared motors) also adds somewhat to the motor-heating, but owing to the variable nature of such losses they are generally neglected in making calculations.
- 339 2. *Method by Continuous Capacity of Motor.* The essential losses in the motor, as found in the typical run, are in most cases those in the motor windings and in the core. The mean service conditions may be expressed in terms of the current which would produce the same losses in the motor windings and in the voltage which, with the current, would produce the same core losses as the average in service. The continuous capacity of the motor is given in terms of the amperes which it will carry when run on the testing stand—with covers on or off, as specified—at different voltages, say, 40, 60, 80 and 100 per cent of

the rated voltage—with a temperature rise not exceeding 90° at the commutator and 75° at any other part, provided the resistance of no electric circuit in the motor increase more than 40 per cent. A comparison of the equivalent service conditions with the continuous capacity of the motor will determine whether the service requirements are within the safe capacity of the motor.

- 340 This method affords a ready means of determining whether a specified service is within the capacity of a given motor and it is also a convenient approximate method for comparing the service capacities of different motors.

APPENDIX C.—PHOTOMETRY AND LAMPS.

- 341 *Candle-Power.* The luminous intensity of sources of light is expressed in candle-power. The unit of candle-power should be derived from the standards maintained by the National Bureau of Standards at Washington, D. C., which standard unit of candle-power equals 100/88 of the Hefner unit under Reichsanstalt standard conditions for the Hefner. In practical measurements seasoned and carefully standardized incandescent lamps are more reliable and accurate than the primary standard.
- 342 *Candle-Lumen.* The total flux of light from a source is equal to its mean spherical intensity multiplied by 4π . The unit of flux is called the candle-lumen. A candle-lumen is the $\frac{1}{4\pi}$ th part of the total flux of light emitted by a source having a mean spherical intensity of one candle-power.
- 343 *Candle-Meter.* The unit of illumination is the candle-meter. This is the normal illumination produced by one unit of candle-power at a distance of one metre.
- 344 *a. Candle-Foot.* Illumination is occasionally expressed in candle-feet. A candle-foot is the normal illumination produced by one unit of candle-power at a distance of one foot.
- 345 1 candle-foot = 10.764 candle-metres.
- 346 The use of the candle-metre unit is preferable and is recommended. The *Efficiency of Electric Lamps* is properly stated in terms of mean spherical candle-power per watt at lamp terminals. This use of the term efficiency is to be considered as special, and not to be confused with the generally accepted definition of efficiency in Sec. 85.
- 347 *a. Efficiency, Auxiliary Devices.* In illuminants requiring auxiliary power-consuming devices outside of the luminous body, such as steady-ing resistances in constant potential arc lamps, a distinction should be made between the net efficiency of the luminous source and the gross efficiency of the lamp. This distinction should always be stated. The gross efficiency should include the power consumed in the auxiliary resistance, etc.. The net efficiency should, however, include the power consumed in the controlling mechanism of the lamp itself. Comparison between such sources of light should be made on the basis of gross efficiency, since the power consumed in the auxiliary device is essential to the operation.
- 348 *b. A Standard Circuit Voltage* of 110 volts, or a multiple thereof may be assumed, except where expressly stated otherwise.
- 349 *Watts per Candle.* The specific consumption of an electric lamp is its watt consumption per mean spherical candle-power. "Watt per candle" is the term used commercially in connection with incandescent lamps, and denotes, watts per mean horizontal candle-power.
- 350 *Photometric Tests* in which the results are stated in candle-power should always be made at such a distance from the source of light that the latter may be regarded as practically a point. Where tests are made at shorter distances, as for example in the measurement of lamps with reflectors, the result should always be given as "apparent candle-power" at the distance employed, which distance should always be specifically stated.
- 351 *Basis for Comparison.* Either the total flux of light in candle-lumens, or the mean spherical candle-power, should always be used as the basis for comparing various luminous sources with each other, unless there is a clear understanding or statement to the contrary.
- 352 *Incandescent Lamps, Rating.* It is customary to rate incandescent lamps on the basis of their mean horizontal candle-power; but in com-

paring incandescent lamps in which the relative distribution of luminous intensity differs, the comparison should be based on their total flux of light measured in lumens, or on their mean spherical candle-power.

353 The *Spherical Reduction-Factor* of a lamp

$$= \frac{\text{mean spherical candle-power}}{\text{mean horizontal candle-power}}$$

354 The *Total Flux* of light in candle-lumens emitted by a lamp = $4\pi \times$ mean horizontal candle-power $\times$ spherical reduction-factor.

355 The *Spherical Reduction-Factor* should only be used when properly determined for the particular type and characteristics of each lamp. The spherical reduction-factor permits of substantially accurate comparisons being made between the mean spherical candle-powers of different types of incandescent lamps, and may be used in the absence of proper facilities for direct measurement of mean spherical intensity.

356 "*Reading Distance*." Where standard photometric measurements are impracticable, approximate measurements of illuminants such as street lamps may be made by comparing their "reading distances;" i. e., by determining alternately the distances at which an ordinary size of reading print can just be read, by the same person or persons, when all other light is screened. The angle below the horizontal at which the measurement is made should be specified when it exceeds 15° .

357 In *Comparing Different Luminous Sources* not only should their candle-power be compared, but also their relative form, intrinsic brilliancy, distribution of illumination and character of light.

APPENDIX D.—SPARKING DISTANCES.

358 Table of Sparking Distances in Air between Opposed Sharp Needle-Points, for Various Effective Sinusoidal Voltages, in inches and in centimeters. The table applies to the conditions specified in Secs. 240-246.

20.....	0.3875	46.....	0.3520
21.....	0.3860	47.....	0.3508
22.....	0.3845	48.....	0.3495
23.....	0.3830	49.....	0.3483
24.....	0.3815	50.....	0.3471
25.....	0.3801		

The fundamental relation between the increase of resistance in copper and the rise of temperature may be taken as

$$R_t = R_0 (1 + 0.0042 t)$$

where R_0 is the resistance of the copper conductor at 0°C . and R_t is the corresponding resistance at $t^\circ\text{C}$. This is equivalent to taking a temperature coefficient of 0.42% per deg. C. temperature rise above 0°C . For initial temperatures other than 0°C ., a similar formula may be used substituting the coefficients in the above table corresponding to the actual initial temperature. The formula thus becomes at 25°C .

$$R_{t+r} = R_t \left(1 + \frac{0.3801 r}{100} \right)$$

where R_t is the initial resistance at 25°C . R_{t+r} the final resistance and r the temperature rise above 25°C .

In order to find the temperature rise in degrees Centigrade from the initial resistance R_t at the initial temperature $t^\circ\text{C}$. and the final resistance R_{t+r} we may use the formula

$$r = (238.1 + t) \left(\frac{R_{t+r}}{R_t} - 1 \right) \text{ degrees C.}$$

See Sec. 265.

EXCERPTS AND REFERENCES.

Generators and Transformers for the Bay Counties Power Co., Cal. (By E. Heltmann and W. Currie. Eng. News, Nov. 21, 1901).—Illustrated.

Electric Light and Power Plant of Brigham City, Utah (By W. P. Hardesty. Eng. News, Sept. 7, 1905).—Illustrations: Power house; iron-work for gates for diverting dam; concrete anchorage for steel pressure supply pipe on slope; diverting dam and intake; details wood-stave pipe; cast-iron hub for connecting steel pipe with wood stave pipe.

Gas Engine Electric Plant as Auxiliary and Reserve for a Long-Distance Transmission System (Eng. News, Sept. 14, 1905).

A High Head Water Power Electric Plant on the Animas River, Colo. (By G. M. Peek. Eng. News, Jan. 4, 1906).—Illustrations: Cross-section of power house; reinforced-concrete pole with spread base, for single 3-phase power transmission line; four-post reinforced-concrete tower with prismatic base, for single 3-phase power transmission line.

Transmission and Distributing System, Long Island R. R. (Eng. News, June 14, 1906).—Illustrations: Top of steel transmission line pole; strain insulators for transmission line cables; details of third-rail guard and supports; standard wooden side approach block construction; standard arrangement of third-rail connecting cables at public crossings.

Cost of Construction and Operating Expenses of the Municipal Electric Lighting Plant at Burlington, Vt. (Eng. News, May 30, 1907).—Six tables of costs.

Some New Methods in High Tension Line Construction (By H. W. Buck. Eng. News, Aug. 8, 1907).—Illustrated. See, also, Paper by E. M. Hewlett, in same issue.

The McCall Ferry Hydro-Electric Power Plant on the Susquehanna

River (Eng. News, Sept. 12, 1907).—Illustrations: Alternate dam sections, showing expansion joints and butt blocks for steel forms; details of steel forms; details of steel traveler; concrete mixer plant; section through power house.

Concrete Telegraph Poles (Eng. Rec., Dec. 17, 1910), 17½ ft. high above the roof have been erected on one of the buildings of the U. S. Aluminum Co., at Niagara Falls. They are 16" sq. at base, 10" sq. at top and reinforced with eight ½" bars bound with ½" hoops 18" c.c.

Cost of Constructing Steam-Driven Electric Power Plants (By F. Koester. Eng. News, Dec. 19, 1907).—*Superstructure*.—\$15 to \$25 for plants up to 5000 K W.; \$15 where there is a compact arrangement with walls of common brick, wooden doors and window frames, steel roof trusses supported by the walls and a roof of the cheapest construction, such as corrugated iron, tin, etc.; about \$20 to \$25 per K W. for construction of higher grade masonry with fireproof windows and doors, roof trusses carried by steel columns which at the same time carry the crane runway, and the roof itself consisting of reinforced-concrete covered by tar and gravel. The cost of superstructure for large size plants usually runs from \$10 to \$20 per K W.; these are constructed of self-supporting steel skeleton and self-supporting walls. The superstructure at \$20 per K W. may embrace multiple boiler floors, while those at \$10 per K W. cover single boiler floor plants only. *Chimney*.—A radial brick chimney for large size power plants may be built for \$1.75 to \$2.25 per K W. Reinforced-concrete chimneys and plate steel chimneys may cost from \$1.50 to \$2 per K W. *Coal and Ash Handling Systems*.—Experience shows that the figures for equipment for handling coal and ashes range from \$1.50 to \$3 per K W. *Boilers*.—The cost of water tube boilers ranges from \$8 to \$10 per K W., depending upon the square feet of heating surface in the boiler. These figures do not include mechanical stokers, for which from \$2 to \$3 may be assumed. Breeching, of course, is also a separate item and varies considerably as to cost per K W. The boiler setting is included in the above cost. *Blowers*.—In many of the modern power plants, especially plants for railway purposes, forced or induced draft is adopted. The blowers are usually steam-driven. The cost of such equipment is about \$1 per K W. *Economizers*.—Where economizers are installed of sufficient capacity to heat the water to 200° or 220° F. such apparatus costs about \$2 per K W., provided that there are not too many additional smoke flues necessary for by-passing, etc. *Boiler Feed Pumps*.—The cost of such pumps alone is some 50 cents per K W. When storage tanks are necessary the cost of the combined outfit amounts to 75 cents or \$1, depending on the number and size of the tanks. *Piping*.—From \$2 to \$6 per K W. For plants of 10,000 to 20,000-K W. capacity, the piping system not being elaborate but sufficient for continuous operation, \$2.50 to \$2.75 has covered the cost. This includes a high grade of covering for steam piping valued at about 20 cts. per K W. *Prime Movers*.—A 5000-K W. turbo-generator should cost from \$20 to \$22 per K W. Reciprocating engines of this capacity are sold roughly at the same price, and about \$10 per K W. needs to be added for the generator. The total cost for smaller units, 600 to 3000 K W. capacity, is from \$20 to \$25 per K W., whether they consist of turbine or reciprocating-engine apparatus. *Condensers*.—The cost of jet condenser equipment runs from \$3 to \$5 per K W., depending upon the type of pump used. The cost of surface condenser apparatus will vary from \$5 to \$8, depending partly upon the vacuum to be carried and whether the casing necessary forms part of the condenser equipment. *Exciters*.—A steam-driven exciter unit costs from 35 cts. to 40 cts. per K W. If a condenser should be installed in connection with it the cost may run as high at 70 cts. per K W., assuming that the exciter capacity is, approximately, 1% the total capacity of the plant. *Switchboards*.—For a high tension voltage the cost will run from \$2 to \$3.50, which for a low tension voltage (2,300 volts or lower) the switchboard equipment may be obtained for \$1 to \$2 per K W., depending largely upon the system of wiring adopted. *Miscellaneous*.—Traveling cranes, 25 or 50 cts. per K W.; smaller items, like house pumps, water meters, blow-off tanks, painting, supervision, etc., from \$1 to \$2 per K W. *Tabulations*.—A summary of the preceding figures is shown in the table below, to which should be added the engineering fee. All these figures represent costs (per K W.) of plants of large capacity, but some have cost as high as \$125 or even, in an exceptional case, \$150 per K W.

COST OF STEAM PLANTS OF LARGE CAPACITY.

Items.	Cost of Steam Turbine Plants. per K W.		Cost of Reciprocating Engine Plants per K W.	
Excavations and foundations.....	\$ 2.00	to \$2.50	\$ 3.00	to \$5.00
Building.....	10.00	15.00	10.00	20.00

71.—MISCELLANEOUS DATA AND ILLUSTRATIONS.

DERRICKS AND CRANES.

Description.	Eng. News.
A 30-ton gantry crane for C. & O. Ry. wharves	Sept. 19, '001.
Modern types of cranes for shipyard service	May 28, '01.
A 30-ton-locomotive crane; a 5-ton derrick crane	Nov. 20, '02.
An electric traveling crane with transfer carriage	May 7, '03.
The 120-ton floating derrick for the Norfolk Navy Yard	June 25, '03.
Portable pneumatic revolving cranes	July 23, '03.
Electric pillar cranes for handling cupola charges	July 30, '03.
A gantry crane with double cantilever bridge	Nov. 26, '03.
A 10-ton stiff-leg der. with ball and socket foot-block bearing	Sept. 22, '04.
Ore-unlocking machines for use at receiving docks	Aug. 3, '05.
Recent heavy cranes in English shops	Aug. 29, '07.
A reversible hoist for elevators and derricks on construction	July 2, '08.
A combined gantry crane and coal elevator	Sept. 17, '08.
Traveling cranes equipped with scales	June 17, '09.
	Eng. Rec.
Steel guyed derrick (mast 70 ft.) for building erection	Mar. 27, '09.
Details of steel stiff-leg derrick	April 23, '10.
A detachable seat for a boom derrick	June 18, '10.
Derrick tower for erecting the Montana capitol	Aug. 13, '10.

CHIMNEYS.

	Eng. News.
Section and plan of concrete chimney in Switzerland	Sept. 19, '01.
Steel chimneys for power station of St. Louis Transit Co.	Dec. 19, '01.
The design of self-supporting steel chimneys	July 20, '05.
Details of 300-ft. chimney of reinforced-concrete	Aug. 3, '05.
A 350-ft. brick chimney for acid chemical gases	Feb. 15, '06.
The design of reinforced-concrete chimneys	Jan. 3, '07.
Method of building a steel chimney	Mar. 14, '07.
Lightning protection for power plant chimneys. U.S. Navy. Yds.	Aug. 22, '07.
Heat expansion stresses in chimneys. Not illustrated	Mar. 5, '08.
Wind stresses in reinforced-concrete chimneys. Diagram	Sept. 10, '08.
Largest Chimney in the world: 50' x 50'	Nov. 26, '08.
Tapering concrete chimney, 258 ft. high	Jan. 13, '10.
	Eng. Rec.
Underpinning a leaning chimney, illustrated	July 3, '09.

MECHANISM AND GEARING.

	Eng. News.
High-speed toothed gearing	Feb. 28, '01.
Chains and chain gearing	Sept. 5, '01.
Two new power transmission devices	June 8, '05.
A mammoth sheave wood block: ht., 53"; wt., 640 lbs.	Mar. 21, '07.
Friction coefficient of wire rope drives	June 27, '07.
The Schmidt silent drive chain	Nov. 28, '07.
The design of friction clutches (mainly for automobiles)	Oct. 1, '08.

MARINE ENGINEERING.

	Eng. News.
A comparison of typical marine engines	Aug. 29, '01.
Cunningham-Seaton system of coaling war vessels at sea	Jan. 21, '04.
Notes on design of steamships Minnesota and Dakota	Sept. 1, '04.
Half cross-section of car-ferry steamer "Detroit;" M. C. R. R.	May 4, '05.

Description.

Experience in the design of marine screw propellers
 A pneumatic submarine signalling bell
 Ocean steamers with steam turbines
 The Cunard steamship "Mauretania"
 Steel barges for transporting steel products, O. and Miss. R.
 Reinforced-concrete barges on the Panama Canal

METAL SPRINGS.

	Eng. News.
New Helical Spring Formulas (following is excerpt)	Jan. 7, '09.

New Helical Spring Formulas have been arranged by Mr. Chester B. Albree and are explained in his paper "Spring Formulas Simplified," which

is published in the November issue of the "Proceedings" of the Engineers' Society of Western Pennsylvania. These are not strictly new, being derived from the well-known Reuleaux' formulas:

$$P = S \frac{\pi d^3}{16 R}$$

$$F = \frac{32 P R^2 L}{\pi G d^4}$$

in which R = radius of coil to center of wire,

L = uncoiled length of wire,

and the other symbols correspond to those used below. The process of simplification is explained by Mr. Albree, in part, as follows:

In comparing the various formulas, it was found that certain quantities could be combined giving formulas of much simpler character and yet equally exact. This was accomplished by cancellations and reductions, eliminating the third and fourth powers and replacing them with areas, diameters and constants. This is done with the intention of rendering the solution of helical spring problems easy for anyone having at hand standard tables of areas and decimal equivalents. The writer is not in the spring manufacturing business and is not an authority on the subject. The formulas derived with the terms used are given below:

$$P = \frac{a d S}{2 D}$$

$$\frac{P}{W} = \frac{f}{f_2} = \frac{F}{F_2}$$

$$f = \frac{D^2}{40 d} \text{ for } S = 100,000 \text{ lbs.}$$

$$= \frac{D^2}{50 d} \text{ for } S = 80,000 \text{ lbs.}$$

$$= \frac{D^2}{67 d} \text{ for } S = 60,000 \text{ lbs.}$$

$$n = \frac{H}{f + d} - 1$$

$$F_2 = n \frac{f W}{P} = n \frac{D^2 W}{40 d p}$$

in which

P = closing, or maximum permissible, load of spring.
 S = torsional strain, outer fiber.
 W = any load on spring.
 f = deflection of one coil under closing load.
 f_2 = deflection under any load.
 F = total deflection under closing load.
 F_2 = total deflection under any load.
 d = diam. of bar of wire.
 a = area of bar or wire.
 D = diam. of coil, center to center of bar or wire.
 H = free height of coiled spring.
 n = number of free coils.
 G = modulus of torsion.
 $= 12,500,000 \text{ lbs.}$

The formulas are based on a spring designed so that when it is closed under a certain load, the strain S , selected, will be reached. The deflection formulas give the pitch of coils to produce strain S , when closed. With what is known ordinarily as "spring steel," it is safe to use $S = 100,000 \text{ lbs.}$, which is the practice of the spring manufacturers of Pittsburg.

The value to be used for S should depend, of course, upon the nature of the work for which the spring is designed and the conditions under which it must operate. The value given above ($S = 100,000 \text{ lbs. per sq. in.}$) is rather high for general conditions. The German engineer's pocketbook, "Hütte," gives $S = 4,500 \text{ kg. per sq. cm.}$ (which is closely equivalent to $64,000 \text{ lbs. per sq. in.}$) for spring steel with fairly constant loading. In springs designed for continual removal and application of load, such as inlet or exhaust-valve springs of gas engines, S should not exceed $45,000 \text{ lbs. per sq. in.}$

Tests of Steel Springs (Proc. A. S. T. M., Vol. VIII., 1908).—The following table shows the effects of different methods of tempering on the elastic limit and modulus of elasticity of steel.

Annealed in lead at	Hardened in oil at	Hardened in water at	Drawn to	Elas. Limit. Lbs. per sq. in.	Mod. of Elas. Lbs. per sq. in.
1400° F.				78 500	27 550 000
.....	1450° F.		560° F.	137 500	28 700 000
.....	1450° F.		560° F.	160 400	27 150 000
.....	1450° F.		400° F.	177 600	29 000 000
.....	1450° F.			187 400	28 610 000
.....		1425° F.	1050° F.	180 700	28 070 000
.....		1425° F.	900° F.	233 900	28 860 000
.....		1425° F.	750° F.	240 800	29 220 000 broke
.....		1425° F.	600° F.	219 800	30 420 000 broke
.....		1425° F.		212 000	29 960 000 broke

METAL HOISTING CHAINS.

Iron, Oval, Open-Link Chains.—The following formulas give the dimensions, weights and strengths of iron chains with open, oval links:—

- Let d = diam., in ins., of round iron used; then—
 $1.5 d$ = transverse inside diam. of oval link, in ins.,
 $2.6 d$ = longitudinal inside diam. of oval link, in ins.,
 l = effective length of each link of chain, in ins.,
 l = length of round iron in each link, in ins.,
 $= 9.475 d$;
 w_0 = weight of each link, in lbs.,
 $= 0.2225 l d^2$;
 $= 2.108 d^3$;
 W' = weight per lin. ft. of chain, in lbs.,
 $= 9.73 d^3$;
 S = ultimate strength of chain, in lbs.,
 $= 1.625 \times$ strength of single rod of diam. d .

GLOSSARY.

(See, also, Index, page 1530, etc.)

A.

Abaciscus.—A diminutive of abacus.

Abacus.—The flat slab (plinth) forming the upper member of the capital of a column to support the architrave.

Abscissa.—The horizontal or x distance, measured parallel with the horizontal axis X , from the vertical or inclined co-ordinate axis Y to any point on a curve whose ordinate is y ; x and y are co-ordinates to any point on a curve, measured from the *origin* or from the axes Y and X . See Analytic Geometry, page 256.

Acclivity.—An upward slope or inclination of the ground; opposed to *declivity*, or a slope considered as descending.

Adit.—A "horizontal" excavation or drift, specially used to drain or operate a mine; it is not continuous as a *tunnel* proper, which strictly has two openings. Word *tunnel* often wrongly used for *adit*.

Adze.—A tool with a curved blade placed at right angle to the position of an axe blade, and used by ship- and bridge carpenters in dressing the top surfaces of timber, ties, etc.

Alternate.—To pass from one state, as motion or position, to a second, then back to the first, and so on in rotation.

Alternations.—A complete alternation is a change in the direction of a current in a circuit from its former direction back again to that direction; symbol $\sim$.

Alternator.—A common term for an alternate current dynamo.

Ammeter.—An instrument for measuring the amperes of a current.

Ampere.—The unit of electric current; symbol, C . $C = \frac{E}{R}$ in which E = electromotive force in volts, and R = resistance in ohms. Current flowing at the rate of one ampere transmits a *quantity* equal to one coulomb per second. One volt-ampere = one watt = $\frac{1}{746}$ horse-power.

Angle-bar.—A bar of angle-iron.

Angle-bead.—A plaster-bead or staff-bead used to protect plaster from injury.

Angle-beam.—A beam with flange set at an angle with the main portion.

Angle-bevel.—Bevel-square.

Angle-block.—In Howe trusses, a "triangular" block of cast-iron or wood set at the junction of the wooden chords and braces, and through which pass the vertical iron or steel rods called *ties*.

Angle-rafter.—A rafter joining the inclined planes of a hipped roof.

Angle-splice.—A splice for rails.

Anneal.—To remove the brittleness of metals, earthenware, glass, etc., by heating them and then allowing them to cool gradually. This toughens, but lowers the tensile strength.

Anticlinal.—The incline or dip of stratified rocks in an upward fold; opposed to *synclinal*.

Anticlinal Axis.—The ridge of an anticlinal.

Apex.—The top junction of two or more lines or members; as the apex of a roof.

A priori.—From that which precedes; from the former.

Apron.—Anything resembling a common apron in form or use. The bridge of a ferry dock. A platform or flooring at a dock entrance. A covering to protect anything, as a dam, from water flowing over it.

Arbor.—An axle or spindle of a pinion or wheel. A mandrel, in lathe turning.

Architrave.—The lower part of an entablature, which rests directly on the columns and supports those parts of the building above. The molding around the extrados of an arch. Sometimes applied to ornamental moldings on faces of jambs and lintels of doors, windows, etc.

Archivolt.—Ornamental molding on extrados of arch.

Armature.—That part of a magnet, dynamo, or motor designed to act upon, or to be acted upon by, the *lines of force* set up by the poles of the field-magnet, in order to produce motion and power (when placed directly at the pole of a permanent magnet it is called a keeper).

Classification (1):

Polarized a.—One made of steel or of another electro magnet and having poles which act upon and are acted upon by the field magnet poles.

Non-polarized a.—One made of soft iron with coils of wire arranged in any form.

Classification (2):

Ring a.—Round and usually of circular cross-section.

Drum a.—An armature of cylindrical form.

Disc a.—

Pole (-or-radial) a.—

Spherical a.—Thomson-Houston type.

Classification (3):

Unipolar a.—One whose polarity is never reversed.

Bipolar a.—One whose polarity is reversed twice in every revolution through the field of the machine.

Multipolar a.—One whose polarity is reversed "multi" times (more than twice) in every revolution.

Armature, Flat-Ring.—A ring armature with a core shaped like a short cylinder.

Armature, Girder.—H-shaped core.

Armature, Toothed-Ring.—A ring armature with core provided with a number of teeth forming spaces between which the armature coils are placed.

Arrester, Lightning.—An apparatus for protecting an electric circuit from lightning.

Arrester, Lightning, Transformer.—A lightning arrester for protecting transformers.

Arris.—The edge-line of an exterior angle formed at the junction of two surfaces meeting.

Arris-gutter.—A V-gutter fixed to the eaves.

Ashlar.—Cut-stone masonry. See *Masonry*, page 432.

Astragal.—A small convex molding in the form of a string of beads.

Axis.—The imaginary line, relatively motionless, about which a rotating body turns.

Axle.—A shaft in the position of the axis of a rotating body.

Axle-box.—The box containing the bearings for the spindle of the axle.

Axle-guard.—The parts of a car in which the axle-box moves vertically when the springs yield.

Axle-seat.—The hole in the car wheel to receive the axle.

Axle-tree.—A fixed axle as for a carriage, the wheels revolving.

Azimuth.—An arc of the horizon intercepted between the meridian of a place and the vertical circle passing through the center of a celestial object. A star's azimuth and altitude determine its exact position.

B.

Backing.—The rough masonry of an arch, abutment or wall, faced with a better class of masonry. Of an arch, it is the course of masonry resting upon the extrados.

Balance-bar = balance-beam.—A long bar or beam attached to canal-lock gates and drawbridges, and used in opening and closing them (usually serving partly as counterbalances).

Balk.—A beam or timber of considerable size. In coal mining: the sudden contraction of a bed of coal, for a certain distance.

Ballast.—Broken stone, gravel, slag, sand, or other suitable material placed on the sub-grade of a roadbed to support the railroad ties, give them lateral stability, and decrease the dust due to passing trains.

Ball-cock.—A lever with a hollow metal ball attached to *one end* and floating in a tank, and operating (as the ball rises and falls with the water) a valve of the cistern at the *other end*.

Ball-valve.—A valve formed by a ball resting on a circular seat when valve is closed; but which is free to rise with the upward pressure of the water.

Barge-board.—Gable-board of a house.

Bars, Bus.—Omnibus bars. (See Bars, Omnibus.)

Bars, Negative-Omnibus.—The bus-bars that are connected with the negative terminal of the dynamos.

Bars, Neutral-Omnibus.—The bus-bars that are connected with the neutral dynamo terminal in a three-wire system of distribution.

Bars, Omnibus.—Heavy bars of conducting material connected directly to the poles of dynamo-electric machines, in electric incandescent light or electric railway installation, and therefore receiving the entire current produced by the machine. Main conductors common to two or more dynamos in an electrical generating plant. (The terms "bus" and "omnibus" bars refer to the fact that the entire or whole current is carried by them.)

Bars, Positive-Omnibus.—The bus-bars that are connected with the positive terminal of the dynamos.

Basculé-bridge.—A counterpoised drawbridge, dating back to medieval times; as the leaf of the span rises, the counterpoise weights descend.

Batter (not batir).—The incline (as of a masonry wall) from the perpendicular; the ratio of horizontal to vertical distance, as 1 in 12=1 in. hor. to 12 ins. vert.

Bay.—A panel of one span; sometimes, one span of several in a bridge. The plain part of anything enclosed or bordered by features in relief.

Bead.—Any small projecting cylindrical, globular or annular body.

Bearing.—The direction of an object by the compass. In mining: the run, course or strike. In architecture: the clear, unsupported span of a beam or timber. In engineering: the actual surface of contact of and with something supported, as of a beam, girder, pivot, axle, etc. In ship-building: the widest part of a vessel below the plank-sheer; also, the line of flotation of a vessel when ready for sea; using in each case the plural, bearings.

Bed-molding = bedding-molding.—A molding of the cornice of an entablature, above the frieze and beneath the corona.

Bed-plate.—A plate (usually of iron or steel) laid on a foundation (say of masonry) and used to give direct support to something (as a machine or bridge) and distribute the stresses quite uniformly (above or below or both).

Beetle.—A heavy wooden mallet (maul) to drive wedges, with handle for swinging; a rammer, with handle set in middle of one head, used by pavers.

Bell-crank.—A right-angle lever pivoted at angle, for changing direction of motion, force, etc.

Bench-mark.—A permanent bench of known or determined elevation with reference to a datum plane, in a line of levels.

Berm (old form, berme) = berm-bank.—A terrace; a strip reserved between top of cut and the waste bank in excavation, or between the bottom of fill and the borrow-pit in embankment; the bank of a canal opposite the tow-path.

Bessemer steel.—Steel made by the pneumatic process, consisting in blowing air through molten pig-iron in a "converter" lined with a refractory material, decarbonizing the iron; later a certain amount of carbon is restored by introducing spiegeleisen or ferromanganese.

Beton.—Hydraulic-cement concrete.

Bevel.—An instrument with a blade and a handle or stock, movable on an adjustable pivot or joint, for including any angle.

Bevel-angle.—Any angle except a right angle.

Bevel-gear.—Toothed wheels which gear at an angle, most often at right angle.

Bilge.—The belly or widest part of a cask; the nearly horizontal part of a ship's bottom, adjacent to the keel.

Bilge-keelson.—A fore-and-aft timber placed inside the bilge to strengthen it.

Bit.—The biting or boring part of a tool. The boring-bit is held or turned by the brace or bit-stock. Old form, "bitt."

Blast-pipe.—The exhaust-pipe of a steam engine; in locomotives, it leads into the smoke stack to create a strong draft.

Board, Switch.—A board provided with a switch or switches, by means of which electric circuits connected therewith may be opened, closed, or interchanged.

Boaster = boasting-chisel.—A broad chisel for rough-hewing and dressing stone. The use of such a chisel is called "boasting."

- Body.**—Consistency or density, as in paints, oils, etc.
- Bolster.**—A "pillow" of timber for various purposes; a short timber or cap-piece resting on a post or column to give more extended bearing to the string-piece or beam.
- Bond.**—The particular arrangement of brick, stone, or timber to give certain specified joints and courses. Friction-resistance of steel in concrete.
- Bonnet.**—A cast-iron plate for covering the opening in a pipe or the opening in the valve-chamber of a pump; the cap or lid of an iron pipe; a wire netting for the smoke stack of a locomotive, to serve as a spark arrester.
- Bore.**—The internal diameter or caliber of a hole, as in a pipe or hollow cylinder; need not have been "bored."
- Borrow-pit.**—The site where excavated material, as earth, is obtained for filling elsewhere.
- Boss.**—A projecting mass, as of stone, to be cut or carved later. The enlarged part in diam. of a shaft for keying a wheel or (if at end) making a coupling.
- Box-drain.**—A rectangular (or square) drain of masonry, or timber, etc., under an embankment (or under ground).
- Brace.**—A strut, or auxiliary compression member in a frame; a bit-stock, or curved handle for holding and turning boring-tools or bits.
- Bracket.**—A projecting piece of wood or metal, fastened to a wall, or ceiling, etc., and used as a support for some object; hence, wall-brackets, hanging-brackets, etc.
- Bracket, Telegraphic.**—A support or cross-piece placed on a telegraph pole for the support of the insulators, which are supported on either *arms* or *brackets*.
- Brake.**—Any mechanical device for retarding motion (as of a vehicle) by means of friction.
- Brake-hanger.**—A bar or link suspending brake-beams and accessories from the truck-frame or from the body of car.
- Brake-head.**—The brake-block (usually cast-iron) fastened to the brake-beam and bearing on the circumference of the car wheel, forming at the same time the brake-shoe.
- Brake-shaft.**—The shaft on which the chain operating a car-brake (by hand) is wound.
- Brass.**—A useful alloy of copper and zinc; harder than copper; malleable and ductile.
- Braze.**—To solder with "hard" solder, as an alloy of "brass and zinc" (= copper and zinc in different proportions than that composing brass).
- Break.**—A want of continuity in a circuit.
- Breaker, Circuit.**—A device for breaking a circuit.
- Break joint.**—To arrange parallel members so the joints will not be opposite; thus, with the splicing of the leaves composing the chord of a Howe truss, or the two rails composing a track, etc.
- Breast-beam.**—The transverse forward beam of a locomotive.
- Breast-board.**—The weighted board or sled used in rope walks to keep the yarns taut while being twisted into a strand.
- Breast-drill.**—A drill-stock having a breast piece against which the workman bears while operating the drill.
- Breasting.**—The (curved) channel in which a breast-wheel turns.
- Breast-line.**—The rope used to connect the pontoons of a floating bridge.
- Breast-wall.**—A (low) retaining wall at the bottom of a slope.
- Breast-wheel.**—A water-wheel with radial floats or buckets on its periphery, the water being confined to the floats by the "breasting" of timber or masonry, nearly touching the wheel.
- Breech.**—The hind part of anything; the angle of a knee-timber, opposite the "throat."
- Brest-summer.**—A lintel; a beam or summer placed to support an upper wall, as over a shop window or door.
- Bricknog.**—A timber framing, as a partition, filled with brickwork.
- Brick-trimmer.**—A brick arch to protect a wooden trimmer in front of a fireplace.
- Bridge-bar.**—The tension bar of a car-coupling.
- Bridge-board = notch-board.**—A notched board of a stair to receive the ends of the wooden steps (treads) and risers.
- Bridge-pit.**—The pit for the counterpoise of a bascule-bridge.
- Bridges.**—Heavy copper wires suitably shaped for connecting the dynamo-electric machines in an incandescent light station to the bus-rods or wires.

- Bronze.**—An alloy of 85% $\pm$ of copper and usually 15% $\mp$ of tin; variable; sometimes no tin; sometimes contains zinc.
- Brush-Holders for Dynamo-Electric Machines.**—Devices for supporting the collecting brushes of dynamo-electric machines. Brushes should be adjusted carefully to speed of machine and resistance of external circuit. Carbon brushes are plates of carbon for leading current to electric motors. Collecting brushes are conducting brushes which bear on the commutator cylinder, and takes off the current generated by the difference of potential in the armature coils. Copper is almost universally employed.
- Bucket-engine.**—An improvised water-wheel for a high fall with scarcity of water, consisting of a series of buckets on an endless chain running over a pair of sprocket-wheels.
- Bucket-lift.**—In mining, a set of iron pipes attached to a lifting-pump.
- Bucket-pitch.**—The circular line intersecting the elbows of the buckets of an overshot water-wheel.
- Bucket-valve.**—The valve at top of the air-pump bucket in a steam engine.
- Bucket-wheel.**—A series of buckets arranged on an endless chain passing over a wheel, for raising water; or, the buckets may be attached to the rim of the wheel.
- Bucking iron.**—A tool for pulverizing ore on a plate called a "bucking-plate."
- Buckram.**—Coarse linen cloth stiffened with glue and used for binding books.
- Buffer.**—An apparatus for deadening the concussion of railway cars.
- Bulkhead.**—A partition; in a ship, to form separate apartments; in a tunnel, conduit or mine, to prevent the passage of water, mud and air. An improvised wharf, sometimes constructed of sunken cribs, to form a basin, or to run parallel with the shore.
- Bull-pump.**—A pumping-engine with piston-rod attached directly to the pumping-rod, the weight of the rods producing the down stroke.
- Bumper-timber.**—A timber to which the cow-catcher of a locomotive is fastened.
- Bumping-post.**—A fender or buffer at the end of a railroad track to stop the cars.
- Bunker.**—See "coal-bunker."
- Bunker-plate.**—An iron plate covering the hole in a ship's deck leading to the coal-bunker.
- Buoy.**—A floating body anchored in a harbor or stream to indicate the positions of objects beneath the surface, as rocks, shoals, etc., or to locate channels. Among the various kinds are spar-buoys, can-buoys, bell-buoys, whistling-buoys, etc. In the U. S., red buoys mark the right-hand, and black buoys the left-hand, side of channels coming into port. Buoys with black and red transverse stripes mark dangers in mid-channel; while buoys with black and white longitudinal stripes indicate fairway. Green buoys indicate sunken wrecks.
- Burnish.**—To polish by friction, as metals.
- Burr-pump = burr-pump = bilge-pump.**—Has a cup-shaped cone of leather fastened to end of pump-rod, the sides collapsing as the rod descends.
- Bush = bushing.**—A lining of harder material fitted into an orifice to reduce wear by friction; used in machinery of all kinds.
- Bushel.**—U. S. standard = 2150.42 cu. ins. British imperial bushel = 2218.192 cu. ins.
- Butt.**—A door-hinge. A large cask, containing 110 imperial gallons.
- Butte.**—A rising ground or mound.
- Butterfly-valve = butterfly-cock.**—Employed in lift-buckets of large water-pumps and for air-pump buckets of condensing steam-engines. It is a double clack-valve or wing-valve, the two wings being hinged to a cross-rib cast in the pump bucket.
- Butt-joint = butting-joint.**—Opposed to lap-joint. A joint formed by the two pieces of metal or timber abutting endwise, and usually spliced together with other pieces.
- Buttress.**—A prop or support of masonry. A bearing or thrusting structure built against a wall to give it stability.
- Buzz-saw.**—A circular saw; it creates a "buzzing" noise.
- By-pass.**—An extra gas- or water-pipe passing around a valve or chamber so as to give some flow when valve or chamber is closed.
- By-wash = by-lead.**—A channel for surplus water from a reservoir or aqueduct, to prevent overflow.

C.

- Cableway.**—A taut suspended cable for conveying loads suspended in a car and moved by a hauling-rope or other device.
- Calisson.**—A water-tight casing used in building the foundation of structures in water too deep for the coffer-dam. It is sunk by under-mining and the masonry is laid on top as it descends into the mud.
- Calcination.**—The process of expelling volatile matter from a substance by heat, and reducing it to a friable state: as carbonate of lime, to lime.
- Caliber = calibre.**—The diameter, especially the inner diameter or bore. In firearms, a 44 caliber rifle is one whose bore is 0.44 in. dia.
- Caliper = calipers.**—An instrument like a pair of dividers, but with curved legs, for measuring inside and outside diameters.
- Calking = caulking.**—The operation of filling seams of vessels with oakum to prevent leaks; or, the joints of cast iron pipes with oakum and lead, the oakum and lead being calked with a calking-iron or chisel, hammered with a calking-mallet.
- Calorimeter.**—An apparatus for measuring the quantity of heat given off by a body, etc.
- Cam.**—A device, usually upon a shaft, for converting a regular motion into an irregular, an alternating, or a reciprocal one. An eccentric. An elliptical lever for raising the ends of drawbridges, when closed, to a firm bearing.
- Camber.**—In a bridge, a slight upward curve in the span, to allow for settling when loaded, or for appearance. In laying cast-iron-pipe culverts under a railroad embankment, they should be jointed or laid in a vertical curve, convex upward, to allow for settlement in the middle.
- Camel.**—A water-tight apparatus which is filled with water, sunk, attached to vessel's bottom, water pumped out, and which then assists in floating the vessel over a shoal, or raising her from wreckage.
- Candle-foot.**—A unit of illumination equal to that produced by a standard candle at a distance of 1 foot. The power is inversely proportional to the square of the distance; thus, the illumination at 3 feet is one-ninth that at 1 foot.
- Candle-power.**—The standard is a spermaceti burning at the rate of 120 grains of sperm per hour.
- Cantilever.**—A block or bracket framed into the wall of the building, projecting from it, and used for supporting a molding, balcony, eaves, etc.
- Capital.**—The top of a column, pillar or pilaster.
- Capstan.**—An apparatus something on the principle of a windlass, but with a vertical axis. The man-power is applied to capstan-bars inserted horizontally in holes near top of windlass, a few turns of the rope, cable or chain being wound around the barrel of the latter. At the bottom of the barrel is a pawl-head with pawls to engage a ratchet-ring secured to the platform.
- Carbonize.**—To combine with carbon, as in the manufacture of steel by the cementation process. Hence the term *carbonisation*.
- Carburize.**—To combine with carbon or a carbon compound. (The vapors of volatile hydrocarbons are often mingled with combustible gases in order to produce higher illuminating power in the latter). The process is called *carburisation*.
- Case-hardening.**—A quick process of cementation or converting the outer surface of iron into steel by heating it in contact with charcoal or some animal matter as bone, hoof parings, or leather.
- Casemate.**—The masonry vault in the rampart of a fortress, or the armored bulkhead in warships, pierced in front with embrasures or port-holes through which guns are fired.
- Casting-plt.**—The part of a foundry where molds are placed and castings made.
- Causeway.**—A raised path or road over bad ground. A raised sidewalk.
- Cavetto.**—A concave molding of at least $\frac{1}{4}$ circle used in cornices, etc. A recessed pattern; opposed to relief.
- Cementation.**—In metallurgy, a process of effecting a desired important chemical change in a substance when heated in contact with another substance. Bar-iron may be made into steel by heating it above redness while embedded in charcoal-powder. Such a process is termed *carburization* by cementation. Decarburization, or the converting of cast-iron into malleable-iron, is effected by embedding the casting in red-hematite powder and keeping it some time at a red heat.

- Cement-copper.**—Copper precipitated by the process of cementation.
- Center—centering.**—The frame supporting an arch during construction.
- Center of oscillation.**—Coincides with the center of percussion.
- Center of percussion.**—That point in a revolving or swinging body, or pendulum, at which if all the mass were concentrated the effect would remain unchanged; the point of greatest impact with another body, remaining immovable without rotation at time of contact if the opposing body is fixed.
- Center-plate.**—A plate which supports a car-body on the center of a truck.
- Center-valve.**—A four-way gas-cock.
- Centrifugal.**—Radiating or outward (force) from the center. Opposed to centripetal.
- Cesspool.**—A shallow well of large diameter for receiving sewerage from isolated buildings. Best constructed in sand or gravel, with linings, say of brick, for the side walls only. Covered top.
- Chamfer.**—To cut away the edge of a square corner so as to form a bevel edge, generally projecting.
- Chamfered.**—Anything in which the surface is beveled. See Side-hatchet.
- Chase.**—To decorate metal-work by tooling.
- Check-nut.**—A nut placed on a screw or bolt to prevent the main nut from turning when in place.
- Check-stop.**—In deep dredging, a device to prevent the dredge-line from breaking when the dredge fouls.
- Check-valve.**—A valve placed in a pipe to prevent the backward flow of the water, steam, or other fluid.
- Chock.**—One of two symmetrical pieces enclosing something between them: one of the jaws of a vice, one of the walls of a vein of ore, one of the sides of a pillow-block, etc.
- Chill.**—A metal mold for making certain kinds or parts of iron castings; the surface in contact with the mold cools rapidly and hardens.
- Chimney-cap.**—A device on top of a chimney which is turned by the wind so the exit-aperture is always to leeward, thus helping the smoke to escape. A chimney jack.
- Chimney-stack.**—Several chimneys carried up together.
- Chisel-draft.**—The dressed edge of a stone, either complete or as a guide in dressing the stone.
- Chock.**—A piece of wood inserted to prevent movement, as the chock nailed on the cap of a trestle between the two lines of stringers.
- Chuck.**—A block or device in a lathe for holding anything to be turned.
- Churn-drill.**—A long stone-drill operated by hand: raised and let fall.
- Cinder.**—A mass of ashes, containing more or less unconsumed coal. Pig-iron slag from a blast-furnace.
- Circuit, Closed-Magnetic.**—A magnetic circuit which lies wholly in iron or other substance of high magnetic permeability. All lines of magnetic force form closed circuits. An iron ring forms a closed-magnetic circuit. Where an air gap is formed, as in the case of a horse-shoe magnet with its keeper, it is called an open-magnetic circuit. In other words a closed circuit is formed by a ring of high magnetic permeability.
- Circuit, Electric.**—The path in which electricity circulates or passes from a given point, around or through a conducting path, to its starting point.
- Circuit, External.**—That part of a circuit which is external to, or outside the electric source.
- Circuit, Magnetic.**—The path through which the lines of magnetic force pass. (They always form closed circuits.)
- Circuit, Short.**—Shunt circuit.
- Clack-valve.**—A hinged valve placed in a clack-box, and consisting of a plate of leather strengthened above by a plate of iron larger in dia. than the main pipe, and below by a plate of iron smaller in dia. than the main pipe. The dia. of box is about $1\frac{1}{2}$ times dia. of pipe. Used in pumping. A flap-valve or clapper.
- Clamp.**—Any instrument used to hold anything or to hold two or more pieces together, by pressure. Various forms for different trades and uses.
- Clapboards.**—Long thin boards, thicker on one edge than on the other, and nailed horizontally on the sides of a house, lapping shingle-fashion.
- Claw.**—A part of a tool resembling a claw (hand).
- Claw-hammer.**—A hammer cleft for drawing nails.
- Claw-wrench.**—A common wrench with one jaw fixed and the other movable.

- Claying-bar.**—In blasting, a rod for driving clay into crevices, to protect the charge.
- Cleat.**—Any piece, as wood or iron, for fastening a rope; or by nailing to other pieces to fasten them together.
- Clevis.**—An iron shaped like a horseshoe, or stirrup, or U, with provision for inserting a bolt across or between the ends in order to form a link.
- Click = clicker.**—A kind of ratchet. A small bar pivoted at one end, free to move backward on a toothed rack, but in moving forward it engages one of the teeth and moves the object forward, leaving it at rest during the backward stroke.
- Climbing-irons = climbers = creepers.**—Iron frames with spikes, for climbing telegraph poles, trees, etc.
- Clincher-built = clinker-built.**—Composed of pieces overlapping one another, as in clincher-built boats where the boards overlap like clapboards.
- Clinker.**—The fused or melted ash formed by the combustion of coal; partially-vitrified bricks.
- Clip.**—A metal clasp, as for holding a bunch of paper, or a Y-level telescope, etc.
- Clip-yoke.**—The small plate through which the ends of a U-shaped clip pass, and serving as washer-plate for the nuts of the clip.
- Cloister.**—A covered walk or arched way around the walls of a building, the outer edge being supported on a series of arcades or arches resting on columns.
- Close-hauled.**—Sailing as close to the wind as possible.
- Clutch.**—A movable coupling, as for connecting or disconnecting the ends of two adjacent shafts to make them revolve together or to allow them to revolve separately. If operating by friction it is called a friction-clutch; by engaging prongs, a bayonet-clutch. The cross-head of a piston rod is a form of clutch.
- Coal-breaker.**—A person occupied in breaking the large masses of coal as they come from the mine; or who operates a machine for this purpose; or the machine itself; or the building or structure in which the breaking is done.
- Coal-bunker.**—A place for storing coal.
- Coal-gas.**—An illuminating-gas obtained by heating coal in closed iron vessels free from air; contains about 46% hydrogen, 35% marsh gas, 7% carbonic acid, 4% olefiant gas, tetrylene, sulphureted hydrogen, nitrogen and carbonic acid and traces of other gases.
- Coal-oil = petroleum = rock-oil.**—By refining, we get kerosene, naphtha, etc.
- Coaming = combing.**—The raised borders or edges of the hatches, to prevent water on the deck of a vessel from running into the hold.
- Coal-tar.**—The thick, black liquid which condenses in pipes when gas is distilled from coal. Contains anthracene, benzol, carbolic acid, creosote, naphtha, naphthalin, paraffin, pitch, etc. Used for metal coatings, as for cast-iron pipe; in making asphalt for pavements, etc.
- Cock.**—A faucet, turn-valve, or valve, for regulating the flow of fluids; as air-cock, gage-cock, feed-cock, etc.
- Cock-brass = cock-metal.**—An alloy of two parts copper and one of lead; used for large vessels, cocks or taps.
- Cock-water.**—Water used to wash away sand from ores.
- Coefficient.**—A quantity, number or constant (as 1/10, 4, b, etc.) used as a multiplier into some algebraic expression or physical property of a substance or condition: The coefficient of friction is the tangent of the angle of repose of a body; the differential coefficient (in the Calculus) is the rate of change of a function; the coefficient c in Kutter's formula $c = v\sqrt{rs}$, is the coefficient of velocity of flow for the particular conditions imposed, as roughness of surface n , hydraulic radius r , and hydraulic slope s ; the coefficient of safety, as δ , means that the conditions allowed are 1/5 the ultimate. "Coefficient" is synonymous with "modulus" in many cases, as "Coef. of Elasticity" = "mod. of elas."
- Coffer-dam.**—A water-tight enclosure built in a body of water in order to exclude the water and maintain a dry space for the construction of foundations, bridge piers, etc. Sheet piling is useful for this purpose.
- Cog.**—The tooth, catch or projection, as of a cog-wheel.
- Cog-rail.**—A rack or rail with cogs, placed between the rails of a track to engage the cogged driving-gear of the locomotive in drawing trains on inclined railways, too steep for ordinary traction. The rack is composed of cogs fastened between two angle-irons.

- Coil, Choking.**—A coil of wire so wound on a core of iron as to possess high self-induction. Such coils are used to obstruct or cut off an alternating current with a loss of power less than with the use of mere ohmic resistance.
- Coil, Electric.**—A convolution of insulated wire through which an electric current may be passed.
- Coil, Impedance.**—A term sometimes applied to a choking-coil. (Self-induction produces impedance.)
- Coil, Induction.**—An apparatus consisting of two parallel coils of insulated wire employed for the production of currents by mutual induction. It consists essentially of a *primary* coil, a *secondary* coil, and an iron core, usually laminated. The primary coil is wound around the core, and over that the secondary coil. The former is composed of thick wire, and the latter of thin wire. If a current is passed through the primary coil its voltage is raised in the secondary coil.
- Coil, Induction, Inverted.**—An induction coil in which the primary coil is made of a long, thin wire, and the secondary coil of a short thick wire. Hence, a current passing through the primary coil induces a current of lower potential in the secondary coil.
- Coil, Magnet.**—A coil of insulated wire surrounding the core of an electromagnet, and through which the magnetizing current is passed.
- Coil, Primary.**—That coil or conductor of an induction coil or transformer, through which the rapidly interrupted or alternate inducing currents are sent.
- Coil, Secondary.**—That coil or conductor of an induction coil or transformer, in which alternating currents are induced by the rapidly interrupted or alternating currents in the primary coil.
- Coil, Shunt.**—A coil placed in a derived or shunt circuit.
- Coils, Armature, or Dynamo-Electric Machine.**—The coils, strips or bars that are wound or placed on the armature core. The wire is as thick as possible consistent with the desired electromotive force without requiring excessive speed of rotation. The armature coils should enclose as many lines of force as possible. If rods or bars are used they should be laminated in planes parallel to the lines of force so as to avoid eddy currents. The coils of pole armatures should be wound near the poles rather than on the middle of the cores. Open-circuit coils or simply open coils are those which are independent of one another, either for a part or the whole revolution. Closed-circuit coils or simply closed coils are connected coils. In alternate current dynamos the separate coils that are used on the armature may be coupled either in *series* or in *multiple-arc* (multiple-arc or multiple circuit means a compound circuit in which all positive poles are joined to one end of a conductor, and all negative poles to the other end.) They are connected in *series* usually in alternate current machines of high electromotive force where the converter is at a considerable distance; and in *parallel* where low electromotive force is sufficient, as for incandescent lamps in multiple arc.
- Coke.**—A useful product of coal, for the manufacture of iron. Coke is the "charcoal" of coal.
- Colatitude.**— 90° minus the Latitude of the place.
- Cold-chisel.**—A tempered steel chisel with a cutting edge for cutting metal.
- Cold-shot-cold-shut.**—In foundry work, small particles of iron found in chilled parts of a casting.
- Collar.**—A ring, or anything resembling a common collar; an enlarged part of a shaft, or the enlarged portion of a car-axle, etc.
- Collar-beam = wind-beam.**—A timber beam stretching horizontally between two rafters (forming a letter A) in order to prevent sagging, etc.
- Collectors of Dynamo-Electric Machines.**—In a restricted sense *collectors* are brushes or points used to carry off the current generated in alternate-current machines, being distinguished from *commutators* which carry off the current generated in continuous-current machines. In other words, commutators change alternate currents, generated on rotation of the armature, to continuous currents, while collectors do not. Nevertheless, the name "collectors" is sometimes used to embrace "commutators".
- Column = pillar.**—A vertical "shaft" set on a "base" and surmounted by a "capital." In classic architecture we have the Doric, Ionic and Corinthian.
- Combustion.**—A rapid oxidation of a combustible substance, caused by the chemical union with the oxygen of the air.

- Commutator.**—A device for changing the direction of an electric current.
- Commutator, Dynamo-Electric Machines.**—That part of a dynamo-electric machine which is designed to cause alternating currents, produced in the armature, to flow in one and the same direction in the external circuit; that is, to change alternate to continuous currents.
- Concrete.**—The compact mass formed by an aggregate of broken stone or other coarse material mixed with a matrix of (hydraulic-cement) mortar. There are other kinds, as asphalt-concrete, etc.
- Concrete rubble-masonry.**—Rubble masonry in which concrete is used instead of the usual cement mortar: for economy of cement.
- Condenser.**—A device for accumulating or condensing, as electricity, water etc. The surface condenser in a steam-engine is one in which the exhaust-steam passes through a large number of pipes immersed in cold water, constantly renewed.
- Conductivity.**—The property which a body or substance has of conducting electricity, heat or sound. It varies with the temperature and the physical stress (as tension) of the substance. In electricity, it varies inversely with the resistance, as $C = E + R$; and is defined as the reciprocal of electric resistance, R .
- Conductor.**—A substance which will permit the passage of an electric current. The term "conductor" is used in a relative sense, as we have no knowledge of any material that is absolutely a non-conductor.
- Conductor, Anti-Induction.**—A conductor so constructed as to avoid excessive inductive effects from neighboring circuits.
- Conductor, Armored.**—One provided with a covering of metal over the insulating covering for protection from abrasion.
- Conductor, Potential of.**—The relation existing between the quantity of electricity in a conductor and its capacity. For a given quantity: the smaller the wire, the higher the potential. For a given conductor: the greater the quantity the higher the potential.
- Cone-gear.**—Two cones transmitting motion by rolling friction.
- Connecting-rod.**—The "rod" which connects the crank of a body having a circular motion, in order to transmit motion or force to or from some other body, as the connecting-rod of a locomotive or of a beam-engine.
- Console.**—A bracket or corbel with ornamental carvings or shape like an S; used for support of cornice, etc. A wall-bracket for supporting machinery.
- Contacts, Lamp.**—Metallic plates or rings connected with the terminals of an incandescent lamp for ready connection with the line.
- Contour-line.**—A line on a topographical map joining points of equal elevation. A 10-ft.-contour map shows contour-lines marking surface elevations 10 ft. apart, vertically.
- Controller.**—Any device used to regulate the flow of air, water, electricity, etc.
- Controlling-nozzle.**—A device for regulating the size of stream issuing from a nozzle.
- Convective, Electric.**—The air particles, or air streams, which are thrown off from the pointed ends of a charged, insulated conductor. These streams act magnetically, and are themselves acted on by magnets.
- Converter.**—A vessel swung on an axis, lined with some refractory material, in which molten pig-iron is converted into Bessemer steel.
- Coping.**—The top or finishing course of a masonry wall, usually projecting a few inches beyond the line of neat-work of the facing, and beveled for appearance and to shed water.
- Corbel.**—A horizontal projecting piece, acting as a cantilever in assisting to support a beam or piece resting or partly resting upon it. In mill-building construction, the columns are often capped with corbels which project a short distance under the superimposed beams. Their utility is questioned by many engineers.
- Corduroy-road.**—A road constructed of logs laid transversely and close together, usually across muddy or marshy ground.
- Core.**—The inner portion or filling of a wall. The inner mold of a casting to make the hollow space, as of a pipe. The iron body of an electromagnet. The comparatively thin wall of masonry constructed in the heart of an earth dam to prevent leakage.
- Core, Armature, Filamentous.**—An armature core, the iron of which consists of wire.
- Core, Armature, H.**—An armature core in the shape of the letter H, generally known as the shuttle- or the girder armature. We also have the I armature.

- Cose, Armature, Lamination of.**—The subdivision of the core of the armature of a dynamo-electric machine into separate insulated plates or strips to prevent eddy currents.
- Core, Armature, of Dynamo-Electric Machine.**—The iron core, on, or around which, the armature coils of a dynamo-electric machine are wound or placed. It is laminated to prevent eddy currents. In *drum*, and in *ring* armatures the laminæ are in the form of thin insulated discs or soft-iron plates; in *pole* armatures, in bundles of insulated wires.
- Core, Armature, Radially-Laminated.**—An armature core, the iron of which consists of thin iron washers.
- Core, Armature, Ribbed.**—A cylindrical armature core provided with longitudinal projections or ribs that serve as spaced channels or grooves for the reception of the armature coils.
- Cornice.**—An ornamental or molded projection at the top of a building-wall, masonry wall, etc.
- Corrugated.**—Wrinkled in regular furrows, as corrugated iron.
- Cotter = cotter-bolt = cotter-key.**—A wedge inserted to fasten or tighten. A split bolt whose ends are spaced apart when inserted as a key.
- Coulomb.**—The unit of electrical *quantity*. That quantity of electricity that will pass in one second in a circuit whose resistance is one ohm, and electric-motive force one volt.
- Coulomb-Volt.**—Volt-coulomb or Joule = 0.7373 foot-pound.
- Counterbrace.**—In a frame, the brace which crosses the main brace and is designed to transmit the compressive stress in a panel due to negative shear, i. e., when the stress in the main brace would change from compression to tension.
- Counterfort.**—A buttress, or portion projecting from the face of a wall to stiffen it.
- Counter-rod = counter.**—In a frame, a rod which crosses the main diagonals and is designed to transmit the tensile stress in a panel due to negative shear, i. e., when the stress in the main diagonals would change from tension to compression.
- Counter-shaft.**—A secondary shaft running parallel with and driven by a main shaft.
- Countersink.**—A drill or bit for reaming or making a countersink (= counter-sunk hole). A hole enlarged at the top to receive the countersunk head of a bolt or rivet, so as to be flush with face of plate.
- Counterweight.**—A weight used to balance another; a counter-poise.
- Coupling.**—A device for connecting two shafts so they will act as one in running. Generally, anything that connects, as couplings for cars.
- Coursing-joint.**—A joint between two courses of masonry.
- Cover.**—The cap-head of an upright steam cylinder.
- Crab.**—A portable windlass for hoisting; used in building operation for hoisting bricks and mortar. A horizontal shaft with one or two cranks for turning by hand, and geared to a drum on which the hoisting rope winds. The whole thing set in a wooden or iron frame.
- Cradle.**—A frame placed under the bottom of a ship, on the "ways," to give support in launching or on marine railways. Any contrivance having a "cradle" form for enclosing or supporting.
- Cramp = cramp-iron.**—A piece of iron bent at the ends for holding together pieces of stone, timber, etc., in structures.
- Crane.**—A machine for moving heavy weights and placing them in any desirable position; hence there must be provision for motion in three directions, as vertical, longitudinal and lateral. The two latter may be combined in a circular motion by a *rotary crane*, consisting of a jib or swinging arm *rigidly attached* to a vertical post and rotating together about the axis of the post. In a *derrick-crane* the top of the post is held in position by guys or guy-ropes. A *traveling crane* is one in which the longitudinal motion is provided for by the whole crane traveling longitudinally on a track, as with the *locomotive crane* and various forms in heavy machine shops; the lateral motion being obtained by the movable hoisting carriage operating on the main transverse girder of the crane.
- Crank.**—A bent arm attached to a shaft or axle and forming a radial leverage for turning. A *single crank* is used only at the end of an axis, as in the common grindstone. A *double crank* is used in the middle of a shaft and has four bends, thus ; or, sometimes used to denote two double cranks for reciprocating motion, thus . See also Bell-crank.

Crematory furnace.—A furnace for burning garbage.

Crest.—The top, as of a dam.

Cross-cut.—In mining, a level driven across so as to connect two other levels.

Cross-hair = cross-wire.—A very fine strand of spider's web or metal wire stretched across the diameter of a telescope to mark the direction of sight on a distant object. Used in transits and levels. Two together, crossing each other at an angle of 90° , form cross-hairs. Two or three arranged horizontally and parallel in a transit are used as stadia wires for measuring distances instead of by chaining.

Cross-head.—The sliding bar at the end of the piston-rod of a steam engine.

Cross-cut saw.—A large saw operated by a man at each end, and used for sawing logs or large timbers *across* the grain. Opposed to *whip-saw* which is used to saw (also by hand) *with* the grain, as planking from logs.

Cross-section.—A section at right angle to the (longest) axis.

Cross-valve.—A valve placed at the junction of two or more pipes.

Crow = crowbar.—An iron bar with end pointed or slightly bent, and used for prying, as a lever, etc.

Crowfoot.—A mark used by surveyors when chaining, consisting of a central line, marking the exact distance, and two flaring lines, forming a sort of arrow-head.

Crown-arch.—The arched plate which supports the crown-sheet of the fire-box of a boiler.

Crown-bar.—One of the bars on which the crown-sheet rests.

Crown-gate.—The head gate of a canal lock.

Crown-glass.—A good quality of common window-glass.

Crown-saw.—A cylindrical saw with teeth on edge of cylinder.

Crown-sheet.—The sheet forming the upper part of the fire-box of the furnace of a steam-boiler.

Crown-tile = hip-tile = ridge-tile.—A bent or curved tile used at the crown as a finish for pan-tile or flat-tile roofs.

Crown-wheel = contrate-wheel = face-wheel.—A wheel with teeth or cogs at right angles with its plane.

Crucible.—A pot for melting metals, ores, etc. The hollow at the bottom of a chemical furnace for collecting the molten metal.

Crucible steel.—Cast-steel.

Crypt.—The part of a church or cathedral below the main floor.

Cupola-furnace.—A furnace for remelting cast-iron.

Cup-valve.—A sort of semi-spherical valve, or balance-valve, over an opening to which it fits when valve is closed.

Curb.—Anything used to curb or check. The outer casing of a turbine-wheel. The wall-plate at the bottom of a dome. The casing of masonry, wood or iron built inside a well that is being sunk. Stones or timber at edge of a well or of a street, etc.

Current, Alternating.—A current which flows alternately in opposite directions; that is, its direction is rapidly reversed.

Current, Assumed Direction of Flow.—The direction the current is assumed to take, i. e., from the positive pole of the source through the circuit to the negative pole of the source.

Current-breaker.—Any device for breaking the circuit of an electrical current.

Current, Constant.—A current that continues to flow in the same direction for some time without varying in strength.

Current, Continuous.—A current which flows in one and the same direction.

Current, Direct.—A continuous current.

Current, Electric.—The quantity of electricity which passes per second through any conductor or circuit; that is, the *rate* of flow. (See *Amps.* *Coulomb.*)

Current, Induced.—The current produced in a conductor by cutting lines of force. It results from differences of potential produced by electro-dynamic induction.

Current-meter.—Any device for measuring the flow of water in streams.

Current-meter.—A form of galvanometer.

Current, Multi-phase.—A rotating current.

Current, Periodic.—A simple periodic current.

Current, Rotating.—A term applied to a current which results by combining a number of alternating currents, whose phases are displaced with respect to one another. A rotating current is sometimes called a *poly-*

phase or multiple-phase current, particularly if there are more currents combined. When three currents are combined the displacement between each set of phases is 120 degrees. A rotary current, unlike an alternating current, possesses, in a certain sense, a definite direction of flow. Its effect on a magnetic needle is to cause rotation.

Current strength.—The product obtained by dividing the electromotive force by the resistance. $C = \frac{E}{R}$. (See *Ampere*.)

Currents, Eddy.—Useless currents produced in the pole-pieces, armatures, field magnet cores of dynamo-electric machines or motors, or other metallic masses, either by their motion through magnetic fields, or by variation in the strength of electric currents flowing near them.

Current-wheel.—A wheel driven by the current of a stream.

Cut-off.—A device for automatically cutting off the steam from the steam-chest to the cylinder before the piston has made its full stroke, the balance of the stroke being made by the expansive force of the steam in the cylinder. A channel cut across a bend thereby shortening the main course of the river.

Cutwater.—The up-stream angle-edge of a bridge pier, designed to more effectively lessen the impact of moving water, ice, logs, etc.

Cyclopean Masonry.—Rubble concrete masonry. Massive concrete in which large rubble stone is added or filled in as the mass is built up; each piece of rubble stone must be thoroughly embedded in, and surrounded by, the concrete.

Cyma = cyme = cima.—A cornice molding having the profile of an ogee, letter S, or curve of contra-flexure.

D.

Dado.—The shaft of a pedestal, between cornice and base.

Damp = fire-damp.—A gas in coal-mines which explodes when mixed with air and ignited; very dangerous. Black-damp or choke-damp is a carbon-dioxide gas in collieries and differs from fire-damp but often found mixed with it. See *Davy*.

Damper.—A metal plate, slide or door, used to regulate the draft of or to a stove or furnace, in order to control the rate of combustion. Many are regulated automatically, as by heat or by steam.

Davy.—A safety-lamp for use in mines.

Dead-head = sinking-head = sprue.—The extra length of metal in a gun-casting, not used because of its inferior quality.

Dead load.—The "dead weight" or non-moving weight of a structure. Opposed to *live load* and *wind load*, but may include *snow load*. The dead load should always be specified in detail. The empty or non-paying rolling-stock of a train.

Dead-oil = heavy oil.—The oils obtained in the distillation of coal-tar above 340° F., and which are heavier than water.

Dead-point.—That position of the crank of an engine when the engine is on its *dead-center*, i. e., when the crank and connecting-rod are in a straight line.

Declination of a heavenly body is its angle north or south of the equator; i. e., it is its distance from the celestial equator measured on a great circle passing through the body and the pole.

Declivity.—A downward slope of ground.

Densimeter.—An apparatus for finding the specific gravity of a substance.

Dentil = dentel.—One of a series of small blocks, uniformly spaced, in a cornice.

Derrick.—A machine for lifting heavy weights, something similar to a crane but having the boom (corresponding to the jib of the crane) pivoted or hinged at its lower end (to the post). It is therefore more convenient than a crane, for use in general building operations. *Floating derricks* are large derricks erected on barges or vessels specially constructed.

Diaphragm.—A thin plate, serving as a partition, placed across a small opening or hollow tube, as the diaphragm of a telephone.

Die.—The cubical part of a pedestal between its cornice and base. An engraved steel for stamping a design. Pieces of hardened steel forming a female screw for cutting screw threads; they are fitted into a die-

- stock and are adjustable for use in cutting threads of different diameters.
- Dike** (formerly *dyke*).—See *Dyke*.
- Dip**.—In geology, the angle which a stratum of rock makes with the horizontal. The *point of dip* is the direction of the compass to which the stratum inclines. The dip of a compass needle from a horizontal plane.
- Disk** = **disc** = **discus**.—A flat circular plate.
- Disk-clutch**.—A form of friction-clutch.
- Dock**.—An inclosed water-space for vessels while handling cargo; a space or structure for loading or unloading cargo, for repairs, etc. See "Wharves, Piers and Docks," page 892.
- Dog** = **dog-iron**.—An iron hook with one or more points at one end, to drive into timber for the purpose of moving it. Used largely in saw-mills. Has many forms and uses. A cramp (which see).
- Donkey-engine**.—A small engine used for performing light work, as pumping water into boilers, hoisting anchors, handling building material, etc.
- Donkey-pump**.—A feed-pump for boilers. An extra pump for special purposes.
- Dormer-window**.—A vertical window in the face of a projection built out from a sloping roof.
- Doubling-frame**.—A machine for winding double silk threads.
- Dovetail**.—One of a series of wedge-like projections or tenons and of corresponding mortises in boards or timbers for fastening them together.
- Dowel**.—A wooden or metallic pin inserted part way into two pieces of wood or stone to unite them.
- Down-draft**.—A downward draft of air in a mine, chimney, etc.
- Draft**.—The vertical depth of water which a vessel requires or "draws." The dressed edge of a stone. See *Chisel-draft*.
- Draw-plate**.—A drilled plate of hard steel, or a drilled ruby or diamond, for drawing wire to reduce its diameter, make it uniform, or shape it. The holes are somewhat conical. The wire may be drawn successively through holes of decreasing diameter.
- Drift**.—A nearly horizontal tunnel in a mine. Loose material, as timber, trees, etc., in a current. In geology, loose rocks, boulders, gravel, sand, etc., which have been deposited on bed rock; *glacial drift* if deposited by glacier.
- Drift** = **drift-pin**.—A long, round, tapering pin of steel, used in enlarging the punched holes in metal plates, or smoothing the inner edges.
- Drift-bolt**.—A steel bolt used in driving out other bolts. A round, steel pin for driving into auger-holes in timbers to fasten them together; bridge-stringers are thus drift-bolted to caps. When pointed it is called a pointed drift-bolt.
- Drip**.—Any small tube or channel to lead water from a structure and let it fall to the ground; as a projecting member of a cornice, or a small channel cut under the edge of a coping.
- Drop**.—One of a series of short cylinders or truncated cones placed in a row in cornices, as ornamental.
- Drum**.—A revolving cylinder around which ropes are wound in hoisting.
- Dry-rot**.—A rot in timber which has not been seasoned sufficiently. Thoroughly seasoned timber will not rot if protected from dampness; or if treated with a preservative the decay will be slow, even in damp places.
- Ductility** of a metal is that property which renders it capable of being extended by drawing, as through a draw-plate, with lessening diameter, and without fracture. Gold is the most ductile; then silver, platinum, iron, copper, palladium, aluminum, zinc, tin, lead.
- Dyke** (more modern spelling is *dike*).—A long bank of earth thrown up to prevent low lands from being overflowed. A levee. In geology, a fissure in rocks, filled with lava or other material while in a molten state.
- Dynamics, Electro**.—That branch of electric science which treats of the action of electric currents on one another and on themselves or on magnets.
- Dynamo**.—Dynamo-electric machine or generator.
- Dyne**.—The unit of force in the centimeter-gram-second system. It is about 1.02 times the weight of a milligram.

E.

- Eccentric**.—A sort of crank device for converting a regular circle motion into an irregular reciprocating straight-line motion. Thus, in the

- steam engine, it consists of a circular disk rigidly attached to a shaft, but not at center of disk, and revolving around with it; the circular disk being surrounded by a loose ring attached to the eccentric rod leading to the valve-gear of the cylinder, thereby regulating the cut-off and making the engine self-acting.
- Electrolysis.**—Chemical decomposition effected by means of an electric current. Water- and gas-pipes are affected by electrolysis when forming the return circuit of electric distribution as in street railways. The electrolytic action occurs when the current jumps *from* the pipe, carrying atoms of metal along with it.
- Electrometer.**—An apparatus for measuring differences of potential.
- Entablature.**—In architecture, a sort of lintel construction supported on columns and extending toward the roof, and comprises the architrave, frieze, and cornice.
- Erg.**—The unit of work or the work done when unit force is overcome through unit distance. A dyne-centimeter.
- Escarpment.**—The abrupt face of natural rock or soil in a cliff or high ridge. In fortifications, ground cut away forming a nearly vertical slope about a position to render it inaccessible.
- Escutcheon.**—The little plate for protecting the keyhole of a door; or the plate to which the handle is attached.
- Expansion-drum.**—A drum with adjustable diameter, used in connection with driving an endless cable.
- Eye.**—A circular hole in a plate, or formed by a loop of iron. The center hole of a wheel on a shaft.
- Eye-bolt.**—A bolt with an eye or ring at one end.
- Eye-piece.**—The lense or combination of lenses in an optical instrument to which the eye is applied.

F.

- Face.**—The front of anything. The face of a valve is the part of the surface which comes in contact with the seat.
- Face-hammer.**—One with a flat face. A hammer with a cutting and blunt end, used in preparing stone for finer tool-work.
- Face-lathe.**—A lathe for turning face-work.
- Face-wheel.**—See *Crown-wheel*.
- Fall—fall-rope.**—The fall of a tackle, or the rope used with pulleys in hoisting. "Fall and tackle" means "block and tackle."
- False-work.**—A temporary structure to aid in the erection of the permanent one.
- Farad.**—The practical unit of electric capacity.
- Farad, Micro.**—The millionth part of a farad.
- Fascines.**—Sticks or brush tied in bundles and used as a protection for river-banks; also used in the construction of sea-walls in connection with piling. Fascines are weighted with stone.
- Fatigue.**—The weakness of metal, as a bar, produced by repeated application of stress well within the breaking load.
- Faucet.**—A device in a pipe for regulating the flow of a liquid. The primitive form is a hollow plug in a cask, with a transverse hole near the outer end to be filled with a hollow plug when not in use.
- Feather.**—A thin rib cast on iron-framing to give it strength. A rib cast on a shaft to fit a corresponding groove in the eye of a wheel. A small steel slip inserted in a shaft and projecting so as to fit the groove in the eye of a wheel. One of two pieces of metal placed in a hole in a stone, which is to be split by driving a "plug" or steel wedge between them. The stone is said to be split by "plug and feather."
- Feather-edge.**—A very thin edge.
- Feather-joint.**—A joint between boards consisting of a small strip, bead or feather fitting into the opposite mortises on the edges of the boards.
- Feeders.**—In a system of distribution by constant potential, as in incandescent electric lighting, the conducting wires extending between the bus-wires or bars, and the junction boxes.
- Feller—felling-machine.**—A machine for cutting standing timber.
- Felling-saw.**—The saw in a felling-machine (See *Feller*.)
- Felloe—felly.**—The wooden rim of a cart wheel, into which the outer ends of the spokes are driven, and around the outer circumference of which the iron tire is fitted.

- Felt.**—A coarse fabric of hair, wool, or wool and fur, matted together by moisture, heat or pressure, but not woven like cloth.
- Fender.**—A bundle of rope or piece of timber hung over the side of a vessel to protect it from injury by rubbing against another vessel or wharf, etc. A guard post at the edge of a pier or wharf.
- Fender-pile.**—One of a series of piles driven to protect a structure or work from injury by concussion resulting from moving bodies.
- Ferro.**—Relating to some compound of which iron is a constituent element.
- Ferrule.**—A metal ring around anything to prevent it from splitting or breaking. A bushing for expanding the end of a flue of a steam-boiler. Many things, in the nature of a ring for protection. A sleeve.
- Ferry-bridge.**—The landing-stage of a ferry.
- Field, Alternating.**—An electrostatic or magnetic field, the positive direction of the lines of force in which is alternately reversed or changed in direction.
- Filler.**—Anything to fill a space or void, as a long narrow plate between the web-plate of a girder and its vertical angle-iron stiffener, sometimes called *filler-plate*. Washers are often used as fillers. A separator, as one of the cast-iron spools near the ends of wooden bridge-stringers to space them one or two inches apart so the air can circulate and keep them seasoned. In painting, the prime coat for filling in between the fibers of the bare wood.
- Fillet.**—A small flat molding, as in a cornice.
- Fire-damp.**—The dangerous and explosive gas from coal in a mine. See *Davy*.
- Fish.**—A long piece of timber or iron secured alongside of another to strengthen it; or at a joint to give stiffness, as one of two fish-plates to stiffen a rail-joint.
- Flag.**—A broad flat stone (flagstone) used for paving. A flag-pole used by surveyors.
- Flange.**—A projecting edge or rim, as the flange of a car-wheel, or of cast-iron flange-pipe (the flanges being bolted together when laid).
- Flap.**—A heavy valve to prevent back tidewater into a-sewer, etc.
- Flap-valve.**—See *Clack-valve*.
- Flashing.**—Sheets of lead, copper, zinc, tin, etc., used on roofs and other places, at the junction of roof and chimney, and at corners, to prevent the rain from leaking through. At a chimney, the upper edge of the sheet of metal is inserted into the joints of the brickwork, so the rain cannot get beneath the flashing, and the rest of the sheet is flattened down against the chimney and passes between two courses of shingles.
- Flask = molding-flask.**—A wooden or iron mold used in foundries to hold the sand and patterns employed in molding and casting. May be in one or two parts, a lower and an upper.
- Flattening-coat.**—The last of four or five coats of paint prepared so as to dry without gloss; it is of pure white lead diluted with spirits of turpentine.
- Flier.**—One of several steps, called *fliers*, in a *straight* flight of stairs. Opposed to *winding stairs*.
- Flint-glass.**—Glass in which the silica is combined with oxid of lead in various proportions, and also containing potash. The lead gives it a higher specific gravity and refractive power, and greater brilliancy.
- Flood-gate.**—A gate designed to open on the rising tide to allow water to fill a basin, and to close at the flood tide to prevent it from flowing out at that point. A gate designed to allow water to escape at floods. Various uses.
- Floor-hanger.**—A bearing-bracket fastened to the floor and used for supporting shafts and countershafts.
- Flume.**—An artificial channel for a stream of water; used in gold-mining, logging, irrigation, etc.
- Flush.**—To drench plentifully with water, as flushing a sewer, gutter, etc.; having the idea of fullness. Even with the surface.
- Flush-box = flush-tank.**—A rectangular box in a water-closet for flushing out the bowl. The outlet-valve is opened by pulling a cord attached to a lever. As the water in the box lowers, the inlet-valve, consisting of a ball-valve or ball-and-lever valve, opens allowing the box to fill; and when full the valve closes automatically through the rise of the ball float.
- Flux.**—Any substance or mixture that will assist the welding or adhesion of two metals by preventing the formation of rust, which is very rapid at such times.

- Fly-wheel.**—A wheel with a heavy rim placed on a revolving shaft of a machine for equalizing the motion of the machinery.
- Follower.**—Any cog-wheel, or other part of a machine, which is driven or which follows the motion of another part called the *leader*.
- Foolscap.**—A folded writing-paper 12 x 16 to 13 x 16 inches in size, making the sheet about 8 x 12 $\frac{1}{2}$.
- Foot-board**—**foot-plate.**—The platform on which the engineer and fireman of a locomotive stand.
- Foot-poundal.**—The unit of energy, equal to a foot-pound + g ($= 32.2 \pm$) = 421402 ergs.
- Force, Electromotive.**—The pressure which tends to move electricity from one place to another. The unit of E. M. F. is the volt, V .
- Force, Lines of.**—A term applied to the strength of a magnetic or electromagnetic circuit. They reach between the opposite poles which produce them, and never intersect. They lie at right-angle with the direction of ether waves.
- Forceps.**—Tongs, pincers or pliers for seizing and manipulating things which it would be impracticable to handle with the fingers.
- Forebay.**—That part of a mill-race (channel where the water flows from the dam to the mill-wheel) where the water flows upon the wheel. The penstock.
- Forge.**—An open furnace provided with a bellows for heating metal to be hammered or forged into shape. Portable forges are used for heating rivets in bridge-erection. A hearth or furnace for making malleable iron by the "direct process." A forging-machine is called a drop-press and operates with a hammer, by power.
- Forge-roll.**—One of a series of rolls for rolling slabs or blooms into puddled bars.
- Forging-machine.**—A machine for forging metal, usually heated.
- Foundry iron.**—Iron containing sufficient carbon for casting.
- Four-way cock.**—A cock or valve with four passages: two in the plug and four for delivery.
- Foxtail**—**fox-wedge.**—A wedge inserted into the end of a pin or bolt so that when the latter is driven to the bottom of the hole the wedge will be forced into the pin, spreading the end of the pin and making it secure against withdrawal.
- Frame.**—Any construction composed of parts fitted together and designed to support itself or other things.
- Friability.**—The quality of being friable, i. e., easily broken or crumbled.
- Friction.**—The resistance to the relative motion of surfaces of bodies in contact: *sliding* friction if one body tends to slide on another; and *rolling* friction if the body is on wheels or rollers, as the rolling friction of a train is say 7 or 8 lbs. per ton. The angle of friction, called the *angle of repose*, is the angle of inclination (with the horizontal) of a surface at which a body will just tend to overcome the frictional resistance and begin to slide, by the force of gravity. The *coefficients of friction* is the tangent of the angle of repose. The friction of liquids is more or less associated with viscosity.
- Friction-balls.**—Balls used to reduce friction of moving parts, as in bicycles and some movable bridges; such bearings are called *ball-bearings*.
- Friction-brake.**—A brake acting by friction.
- Friction-gearing.**—A gearing of wheels imparting motion one to another by the friction of contact alone. They can be thrown in and out of contact readily; when in gear or contact they are called *friction-tight*.
- Friction-rollers.**—Cylinders used to reduce friction of moving parts, as the rollers of a movable land pile-driver.
- Friction-wheels.**—Wheels especially designed to reduce friction of moving parts; or to provide for excess of stress in machinery, as dredging, by allowing the outer rim of wheel to give way to all stress in excess of the frictional resistance on the inner section of the rim.
- Frieze.**—In architecture, the decorative feature of an entablature between the architrave and cornice; also similar decorative features elsewhere.
- Frustum.**—That part next to the base when the top is cut off, as of a cone.
- Fulcrum.**—The point of rest or support of a lever when lifting a body. The support itself.
- Furring.**—Strips nailed on to a wall for subsequent lathing and plastering; or to the bottoms of joists and rafters to bring them to a level surface. The placing of said strips.
- Fuse**—**fuze.**—A slow-burning tube-like or rope-like attachment to an

explosive charge. A *time-fuse* is one which will explode the charge at a certain time. Electric fuses (fired by a spark caused by a break in the electric circuit) are most frequently used for blasting, in work of magnitude. *To fuse* is to melt and blend together.

Fusible-plug.—A plug of fusible metal placed in the shell of a boiler of a steam-engine, and intended to melt and allow the steam to escape when a dangerously high temperature is reached.

Fusion-point.—The temperature at which a substance melts.

G.

Gable.—The vertical end of a triangular- or pitched roof; the triangular canopy over a window. The gable-end of a house is the end-wall.

Gad.—A pointed steel bar or shorter tool for driving into anything and loosening it.

Gadding-machine = gadder.—In quarrying, a movable platform on which a steam-drill is mounted.

Gage = gauge.—An instrument for determining the dimensions, quantity, distance, force, capacity, etc., of anything; or the measurement itself. The gage of a wire is its diameter; in shingling, it is the exposed length of the slate, tile, etc., below the lap; in gunnery, the bore of a gun.

Gage-saw.—A saw with a gage-bar to determine the depth of kerf.

Gage-stuff = gaged-stuff.—In plastering, a plaster of Paris mixture for quick-setting, in making moldings, etc.

Gallon.—Four quarts. U. S. gallon = 231 cu. ins. = 3.7853 liters = capacity of a cylinder 7" dia. and 6" high; more accurately, such a cylinder has a capacity of 230.90706 cu. ins., or 0.9996 gallon, or almost exactly one part in 2310 too small.

Gallows-frame.—The frame for supporting the beam of a beam-engine. The structure for supporting the pulleys and cage in a mine shaft.

Gang-drill.—A machine containing a number of vertical drills in the same head.

Gang-plank = gang-board.—A plank with cleats nailed on transversely for steps and used as an inclined stair.

Gap-window.—A long narrow window.

Gas-compressor.—A pump for compressing coal-gas into reservoirs for railroad-cars, etc.

Gasket.—Any fibrous or soft substance used for packing, in machinery. The circular collar used when pouring lead around lead-pipe joints.

Gas-meter.—An apparatus for measuring the flow of illuminating gas in pipes, etc.

Gate.—A valve. When placed at the headworks of a water supply it is called a head-gate.

Gate-house.—A small house in which the gate of a reservoir is situated and operated.

Gauss.—The unit of intensity of magnetic field.

Generator, Dynamo-Electric.—An apparatus for producing electricity by the mechanical movement of conductors through a magnetic field, cutting lines of force.

Gear.—The connecting parts in machinery for transmitting motion.

Gearing.—A train of toothed wheels, or worms, belts, ropes, etc., in machinery.

Generator, Motor.—A generator driven by electricity instead of by steam-water, or other power.

Gib.—A wooden support under the roof of a coal-mine. An iron clasp used in connection with a key for clamping pieces together. The arm of a crane. A fixed wedge used with the driving wedge to hold together the brasses at the end of a connecting-rod of an engine.

Bin.—One of the two main uprights of a pile-driver, between which the hammer operates. A machine for separating the seeds from cotton, also called a cotton-gin. A machine with a drum and winding rope, for various purposes as moving houses in streets, etc.

Bin-block.—A tackle-block over which a rope runs, and suspended by a hook attached to it.

Gin-tackle.—A double and a single block used as a system of pulleys for hoisting.

Girder.—A simple or composite beam of larger dimensions than an ordinary beam. Thus, *beam-girder*, *box-girder*, *plate-girder*, etc.

- Glack.**—In fortifications, a gentle slope over which the advancing enemy is brought into a direct line of fire.
- Gland—gland-box.**—A stuffing box. A joint tightly packed and capable of retaining lubricants for a period of time.
- Glaze.**—A vitrifiable substance, as salt, applied to the surface of brick, tile, etc., and giving it a transparent coating. An enamel is an opaque coating.
- Glue.**—A substance having cement properties; the common gelatin boiled out of the hides and hoofs of animals.
- Gooseneck.**—A flexible coupling, or a pipe shaped like the letter S. A nozzle with a universal joint similar to that used on the stand-pipe of a fire-engine.
- Governor.**—An automatic regulator for controlling the supply of steam, water or gas. The compass-shaped two-ball apparatus on an engine; the supply-valve is connected to the levers which are operated by the radial movement of the balls, as the latter revolve faster or slower.
- Grapnel—grapple.**—One or more hooks in a cluster for grasping hold of things in deep water; a grappling-iron.
- Graving-dock.**—A dry-dock for graving or cleaning the bottoms of ships.
- Grillage.**—Two or more courses of heavy timbers laid parallel and at right angle (sometimes notched at their intersections) and usually drift-bolted together, to serve as a foundation resting on piles or on the bottom, and supporting a masonry pier or other structure.
- Grille.**—A grating or open work of metal, usually of wrought-iron, for ornamental work.
- Groin.**—The intersection of simple vaults or arches crossing each other at right angle. A breakwater constructed across a beach to form a protection from the waves and prevent the drifting and washing of sand and mud. Sometimes spelled *Groyne*.
- Groove.**—A long narrow channel as if made by a tool, for something to fit into.
- Ground-ice—anchor-ice.**—Ice formed at the river bottom, prior to surface-freezing.
- Ground-swell.**—A deep swell of the sea caused by a distant or late storm. The surface of a rolling country.
- GROUT.**—Thin mortar poured or forced in joints of masonry.
- Groyne.**—See *Groin*.
- Grubbing-hoe.**—A long-handled instrument for digging up or cutting roots; used in "grubbing." A mattock.
- Gudgeon.**—The metal journal of a horizontal shaft, or that part which turns in the collar.
- Guide-bar.**—One of the two parallel sides fitted on the cross-head of a steam-engine, on which the cross-head slides.
- Guncotton.**—Cotton or other cellulose substances digested in a mixture of nitric and sulphuric acids, or in nitric acid alone. Explodes violently by percussion.
- Gun-metal.**—A bronze for making cannon; now supplanted by cast iron, and more frequently by steel.
- Gun-pendulum.**—An apparatus for determining the strength of gunpowder.
- Gunwale.**—The upper edge of a ship's side.
- Gusset—gusset-plate.**—A triangular or trapezoidal plate riveted to box-girders to stiffen them transversely; or used to connect the ends of steel floor-beams with the web of plate-girders, the gusset extending usually the full height of the girder or nearly so in order to give transverse stiffness. In general: a large steel connecting-plate.
- Guy.**—A rope, rod or chain fastened to anything to keep it from swinging, as the guy of a derrick.
- Gyrate.**—To whirl or revolve about a point or axis.

H.

- Hacking.**—In masonry, the cutting up of large courses into smaller ones for expediency when the stones run small.
- Hack-iron.**—A miners' pick or hack. A chisel for cutting nails.
- Half-trap.**—A sinking bend in a sewer-pipe.
- Halving.**—The notching of two timbers of equal thickness together, either crossing each other or at the ends, so the thickness of joint will be equal to that of one of the timbers.

- Hammer-beam.**—A short beam projecting from the foot of a principal rafter, outward toward the center of the truss but not reaching a similar one from the opposite rafter: used in church roof-trusses.
- Hammer-dressed.**—In stone-cutting, dressed with a pick or pointed hammer.
- Hand-lever.**—In a steam-engine, the lever for starting, stopping or reversing the engine.
- Handcrew.**—A jack, or machine for raising heavy weights.
- Handspike.**—A wooden lever for raising weights or working a windlass or capstan.
- Hand-wheel.**—A form of circular crank, as the hand-wheel of a car-brake.
- Hanger.**—A bracket from the ceiling or wall, or a stand from the floor, with a box and oiling device, for supporting a line of shafting. The plates, straps or yokes at the ends of floor beams, for suspending them to bridge-trusses. *Yoke-hangers* are used in connection with wooden floor-beams and consist of square iron bent over the pin of lower truss, the ends passing down through the floor beam and an iron plate, using a nut and check-nut at each end of hanger. *Plate-hangers* are riveted directly to the ends of steel floor-beams, a hole being drilled in upper end for the truss-pin to pass through. A *hanger-board* is a board for supporting electric arc-lamps, making easy connection poles of lamp and line-circuit.
- Hasp.**—A metal clasp as for a door, with a slot for folding it over a staple, and fastened by a pin or padlock. A metal hook for the same purpose.
- Hatch.**—The opening in a ship's deck leading to the hold; usually termed *hatchway*. The cover of such an opening.
- Haunch.**—The part of one side of an arch between the crown and springing.
- Headbay.**—The water space just above a canal lock.
- Head-block.**—The forward carriage for supporting logs being sawed in a mill. Any block for supporting a pillow-block.
- Header.**—A stone or brick with its longest dimension at right angle to the face of the wall.
- Heading.**—A small passage or opening or driftway excavated in advance in the line of a tunnel to facilitate the work.
- Head-valve.**—The delivery valve in a steam-engine.
- Headway = headroom.**—The clear height of space overhead. In railroading, the clear height above rail to the lower part of an overhead bridge or other structure. Advance or progress in work.
- Heart-cam = heart-wheel.**—A cam-wheel with a heart-shaped channel on face of disk in which a guide-wheel travels at the end of an arm, and used for converting rotary into reciprocal motion.
- Heart-shake.**—Defects in timber, consisting in cracks or shakes extending from the center outward.
- Heat-unit.**—(B.T.U.) The amount of heat required to raise 1 lb. of water through 1° Fahr. See page 1347.
- Hectogram.**—100 grams, equal to 1543.235 grains.
- Hectoliter.**—100 liters, equal to 26.4 U. S. gallons.
- Hectometer.**—100 meters, equal to 328' 1".
- Helve.**—The handle of an ax, hatchet or adz.
- Helver.**—The handle of a mining tool.
- Hematite.**—One of the most valuable of iron ores; red oxid of iron, Fe_2O_3 . Found in large quantities in the Lake Superior region.
- Hemp.**—The fibre of a plant; used for making hemp rope.
- Henry, A.**—The practical unit of self-induction.
- Herring-bone bridging = bridging.**—The diagonal pieces nailed between the floor-joists to give stiffness, by distributing the resistance to the floor loads over several joists.
- Highway.**—A road or way of common right for all to pass.
- Hinge.**—A device for joining two pieces in such a manner that one may be turned or swung around or upon the other, as the hinge of a door or of a trunk. A common hinge consists of two straps or leaves, joined by the pin or pintle passing through the knuckle. A *rising hinge* is one which rises when the door opens, to clear the carpet, and usually closing itself. A *butt hinge* is a common door hinge where the leaves butt against each other.
- Hinge-pin.**—The pin or pintle of a hinge.
- Hip.**—The *external* angle or corner formed at the junction of two sloping roof faces, and supported by a *hip-rafter*. Opposed to *valley*, which is the *internal* angle, and supported by a *valley-rafter*.

- Hip-roof**—**hipped-roof**.—A roof with four sloping faces, rising immediately from the wall-plates and with the same inclinations.
- Hip-tile**.—The tile which saddles the hip of a roof.
- Hitch**.—A kind of knot used in making one rope fast to another or to a spar, boom, post or timber. See p. 668.
- Hoarding**.—An English term for a fence for enclosing a building or materials while building work is in progress; a board fence used as an enclosure.
- Hold-beam**.—One of the transverse beams in the lowest tier of beams in a ship's hold.
- Holding-plate**—**anchor-plate**.—The plate at the anchorage of a cable or guy, through which the cable passes or is secured; the plates being backed with masonry, or loose rocks, earth, etc.
- Hook**.—A bent iron for holding a link, or suspending anything. A *pulley-suspension hook* is an S-hook which can be hung over a beam, and support a pulley from below.
- Hook-block**.—A pulley-block fitted with a hook for suspending it, or weights to it. The *standing part of the hook* is that part attached to the block.
- Hook-bolt**.—A bolt with one end in the form of a hook; used in fastening the wooden floor of a bridge to the iron stringers.
- Hoop**.—A circular band or clasp. Hoops around wooden tanks are often adjustable.
- Horizon**.—The *astronomical* or *celestial horizon* is the great circle of the celestial sphere whose plane is perpendicular to gravity at any station.
- Horse**.—A wooden frame with four legs for supporting staging; many similar things.
- Horse-shovel**.—A road scraper.
- Horsing-iron**—**iron**.—A long-handled calking-iron held by one man and driven by another.
- Hour-circle**.—A circle perpendicular to a north and south-axis, and graduated un-clockwise into 24 radial divisions. Any great circle which passes through the two poles. See *Hour Angle*, page 621.
- Hour, Kilo-Watt**.—A unit of electrical power equal to a kilo-watt maintained for one hour.
- Hour, Watt**.—A unit of electrical work—one watt for one hour.
- Housing**.—A niche in a wall for a statue. The *jaw* of a frame which holds the journal-box or housing-box.
- Housing-frame**.—The frame which holds the rollers, in a rolling-mill.
- Hub**.—The center of a wagon-wheel from which the spokes radiate and through which the axle-tree passes; or, in car-wheels, the metal part in the center to which the paper web is clamped. The bell-end of a pipe.
- Hydrant**—**fire-plug**.—An apparatus with a valve and with hose-connections for drawing water from a main.
- Hydraulic balance**.—A water-wheel regulator.
- Hydraulic jack**.—A jack operated by a plunger or piston against some liquid as oil.
- Hydraulic main**.—In gas-works, a large pipe containing water into which the raw gas is brought, and serving as a purifier and to convey the crude gas to the condenser.
- Hydrocarbon**.—A compound of hydrogen and carbon, alone.
- Hydrometer**.—An instrument for determining the specific gravity of fluids.
- Hygrometer**.—An instrument for determining the humidity of the atmosphere.
- Hygroscope**.—An instrument for determining the approximate humidity of the atmosphere.
- Hysteresis**.—Molecular friction due to magnetic change of stress.

I.

- Ice-breaker**.—A structure built in the water to protect bridge-piers from moving ice.
- Ice-machine**.—A machine for producing ice. Anhydrous ammonia is the solution most used, and is most efficient.
- Idle-wheel**.—In toothed gearing, a wheel placed between two others to preserve the same direction of motion in both of them. In rope transmission of power, a wheel to make the cable sag and preserve its tension.

Impedance.—Opposition to current flow.

$$\text{Impedance} = \sqrt{(\text{Ohmic resistance})^2 + (\text{inductance resistance})^2}.$$

Impost.—The upper part of a wall or column from which an arch springs.

Inch.—2.54 centimeters. One meter = 39.37 inches.

Inductance.—The induction of a circuit on itself, or on other circuits. Self-induction. The practical unit is the *henry*. The coefficient of inductance is a constant quantity which, multiplied by the current strength passing in any coil or circuit will give the induction due to that current. The practical unit of inductance is 1,000,000,000 centimeters. (See *Ohm*.)

Induction, Electro-Dynamic.—Electromotive forces set up by induction in conductors which are either actually or practically moved so as to cut the lines of magnetic force. Flemings' rule:

Induction-pipe.—In a steam-engine, the pipe through which the live steam passes to the steam-chest. The *induction-port* is the opening from the steam-chest into the cylinder. The *induction-valve* is the valve controlling the steam into the cylinder.

Indurate.—To harden, as with *indurated clay*.

Infusorial earth.—Fine white earth composed of minute silicious shells and resembling magnesia. Used as an absorbent in making dynamite (with nitroglycerin).

Ingot.—A cast of metal from a mold (ingot-mold), as pig iron.

Injector.—An apparatus for forcing water into a steam-boiler.

Inscribe.—In geometry, to draw within, as a square within a circle. Opposed to *circumscribe*.

Insulator, Oil.—A fluid insulator filled with oil.

Insulator, Single-Shed.—An insulator with a single inverted cup.

Insulator, Telegraphic or Telephonic.—A non-conducting support of telegraphic, telephonic, electric light or other wires. Insulators are generally made of glass, porcelain or hard rubber, and assume a variety of forms.

Interlocking system of signals.—In railroading, a system of operating switches and signals jointly by means of locking mechanism, operated from a central station, so trainmen can tell the position of the switches from a distance.

Interpolate.—To find the missing number of a series. In many mathematical tables it is desirable to find (usually by simple proportion, but not always) intermediate values to those given, and this is done by interpolation.

Intrados.—The inner line of an arch; the outer line is called the *extrados*.

Invert.—An inverted arch, as the floor of the lock-chamber of a canal, or the lower part of the brick sewer, or the inverted arches used in the foundation walls of buildings in order to distribute the pressure more uniformly.

Ion.—One of the elements of an electrolyte; *anions* are evolved at the anode, and *cations* at the cathode.

Isobar.—A contour-like line on a map, connecting places at which the barometric pressure is the same.

Isochime = isochelm.—A contour-like line on a map, connecting places having the same mean winter temperature.

Isoclinal.—In geology, strata having the same inclination or dip.

Isoclinal lines.—In magnetism, contour-like lines on a map, through points at which the dip of the needle is the same.

Isometric.—In crystallography, that system which is characterized by three equal axes at right angles, and includes the cube.

Isotherm.—A contour-like line on a map, connecting points having the same mean temperature.

J.

Jack.—An instrument for raising weights; "jacking them up". A *screw-jack* consists of a screw or worm working in a thread; a *lever-jack* is a kind of a *ratcheted-jack*. Various forms. See Hydraulic jack.

Jack-engine.—A donkey-engine.

Jack-rafter.—A short rafter, usual in hip-roofs. A sort of sub-rafter or secondary rafter, parallel with the main rafters and supported on the main purlins; used for supporting directly the sub-purlins or sheathing of the roof.

Jack-rib.—A rib in a framed arch or dome shorter than the others.

Jack-timber.—A framing timber shorter than the others as in the floor of a bay.

Jad.—In quarrying, a long deep gash or hole made in quarrying soft rock, as a sort of heading for wedging or blasting the balance. In coal-mining, a "holing" or "benching" so the mass of coal may fall or be loosened by wedging or blasting.

Jadding-pick.—A sort of pick for cutting a jad in a quarry or coal-mine.

Jag-bolt.—A bolt with a barbed shank.

Jamb.—The vertical side of an opening or recess in a wall, as of a door or window, serving to support in part the weight above, as a lintel. A door-jamb, or window-jamb, or fireplace-jamb.

Jamb-post.—The upright post or timber at the side of an opening or jamb.

Jam-nut.—A sort of lock nut, or a nut screwed down on a bolt hard against another nut to prevent the latter from working loose. Used under wooden floor-beams of bridges when suspended by iron hangers.

Jaw.—Anything in the shape or use of a common jaw, as the jaws of a vice, or wrench, or stone-crusher.

Jaw-bit.—A bar under a journal-box for uniting the two pedestals in a car-truck.

Jaw-bolt.—A bolt with a U-shaped head perforated to carry a pin.

Jetty.—A sort of pier or arm constructed in the water to divert the current and protect banks from washing away, or to scour out the channel, or to cause slack-water and deposit of mud in any place. A pier in the ordinary sense of a wharf.

Jews'-harp.—A shackle, or partly-closed link in the shape of a horse-shoe and with eyes and bolt, for connecting the ring of an anchor with the chain or cable.

Jib.—The projecting arm of a crane.

Jig-pin.—In mining, a pin to prevent the turn-beams from turning.

Jig-saw.—A vertical reciprocating saw with a narrow blade for sawing scroll-work in boards.

Jimmy.—A short crow-bar.

Joggle.—A sub-tenon at the end of a framed timber to prevent it from moving laterally. A notch or mortise in a piece of stone or timber, or a key engaging such a notch, to prevent a corresponding piece or counter-part from movement.

Joggle-piece.—A piece like the king-post of a truss.

Jogglework.—In masonry, stones internotched or keyed together, as in light-house construction.

Joggling-table.—A table or machine for dressing or concentrating ore.

Joist.—One of the spaced beams supporting the boards of a floor, as floor-joist; or a ceiling, as ceiling-joist; or the floor of a bridge, as bridge-joists; etc. Where beams act singly or independently they are called girders, especially if larger than common joists.

Joule.—The unit of electric energy or work. A volt-coulomb. One joule = 0.7373 foot-pound. One joule per second = 1 watt.

Journal.—The part of an axle or shaft which rests in the bearings.

Journal-bearing.—The bearing-support of an axle or shaft. In general, it consists of the *brasses*, resting in the pillow-block and inclosed in the journal-box.

Journal-box = housing-box.—The box (cast-iron) which contains the journal (of the car-axle or shaft), the journal-bearing and key, and the oil-packing for lubricating the journal.

- Journal-brass.**—The bearing of the journal. (Metals of different kinds while in rubbing contact will not wear as rapidly as those of the same kind.)
- Jump.**—A step in a masonry course to accommodate a rise or fall in ground level, or slope. Used in buildings.
- Jump-coupling = thimble-coupling = ring-coupling.**—A coupling with a coupling-box consisting of a ring or thimble over the two connected ends of the shaft, the connection being made by pins through thimble and shaft, or by parallel keys feather bedded.
- Jumper.**—A drill used for drilling holes in stone: a short drill worked by a hammer; a long drill, weighted, raised by hand and let fall, and not worked by a hammer.
- Junction-box.**—A chamber connecting lines of pipes or wires.
- Jute.**—A plant producing jute-fiber; swells with moisture and is inferior for rope.

K.

- Kaolin.**—A fine variety of clay or decomposed feldspar.
- Kedge.**—A small anchor with an iron stock.
- Keeper.**—A key which may be inserted in a stationary or sliding bolt or other piece, to keep it in place. An armature of a magnet, or a piece of soft iron across the poles of a magnet when not in use to maintain (or increase) the power.
- Kerf.**—A channel or cut made as by a saw. A saw-kerf.
- Key.**—Anything that locks or holds fast.
- Key-bed = key-seat.**—A groove for a key for locking, as a wheel to a shaft.
- Key-bolt = cotter-bolt.**—A bolt with a key or cotter, instead of a nut.
- Keystone.**—The center stone of an arch ring, at the apex or crown.
- Kibble.**—The bucket of a shaft or mine for hoisting material; the hoisting chain is called the *kibble-chain*.
- Kiln.**—A furnace or large oven for baking, burning or drying, as a brick kiln for burning or baking brick.
- Kiln-dried.**—Anything, as timber, deprived of moisture by treatment in a kiln or furnace.
- Kilogram.**—1,000 grams in weight, equal to 2.20462 lbs.
- Kilogrammeter.**—A unit of work, equal to 7.233 ft.-lbs.
- Kiloliter.**—A unit of capacity, equal to 1,000 liters.
- Kilometer.**—1000 meters.
- Kilowatt.**—1000 watts.
- Kinetic energy.**—Energy in some form of motion.
- King-post = king-piece.**—The vertical post in a truss with two sloping chords meeting the top of post and framed into it. The two chords may be rafters. The middle vertical member of a king-post truss.
- King-rod.**—A rod used in place of a king-post, in a king-truss.
- King-truss = king-post truss.**—A truss framed with a king-post.
- Knee.**—A piece of wood or metal having an angle and used to join two pieces together, giving support and stiffness; as the beam of a ship to a side timber.
- Knee-strap.**—An iron strap used in connection with a knee-timber.
- Knot.**—A fastening with a rope. See page 668.
- Knuckle-joint.**—A flexible joint, as with two adjoining links.
- K. W.**—A contraction for kilo-watt.

L.

- Laboratory.**—A place with suitable apparatus for conducting investigations or experiments.
- Labyrinth.**—A maze, or combination of passages making exit difficult.
- Lacquer = lacker.**—An opaque varnish containing lac.
- Ladder-dredge.**—A dredge with buckets carried on a ladder-like chain.
- Lagging.**—Falling behind. Narrow strips of wood or planking placed outside of and between the ribs of an arch or tunnel to give support to extraneous material. Used in tunnel construction. The outer wooden casing of boilers, or the wooden strips placed on the periphery of a winding drum. Also used in the sense of *sheeting*.
- Lag-screw.**—An iron bolt with a flat square or hexagonal head and with the other end sharp and threaded like a wood-screw; used in fastening small wooden guard-rails to the ties.

- Lamp, Arc.**—An electric lamp, the source of whose light is the voltaic arc, formed between two or more carbon electrodes.
- Lamp, Incandescent.**—An electric lamp in which the light is produced by the electric incandescence of a strip or filament of some refractory substance, generally carbon.
- Lancet-window.**—A long narrow window crowned with an acutely-pointed arch.
- Landing.**—A resting-place or platform at the end of a flight of stairs, or interrupting a series of steps. A place on shore for discharging passengers or freight from water-craft, usually called *landing-place*.
- Landlocked.**—Protected from the wind and waves, as a small body of water nearly shut in by land.
- Landmark.**—A prominent object locating a line or corner of the boundary of a tract of land.
- Lantern-wheel = lantern-pinion = trundle-wheel.**—A sort of drum-like wheel with two parallel heads joined near their peripheries by parallel rods or spindles and so spaced as to engage the cogs of a spur-wheel.
- Lap.**—The length or width of exposed surface partly covered by another, as the lap of shingle or slate in roofing.
- Lap-joint.**—Opposed to *butt-joint*. A joint formed by the leaves overlapping as in the chord of a Howe-truss bridge. If each piece is composed of only one leaf, the ends are halved to form the lap-joint.
- Lap-weld.**—Opposed to *butt-weld*. A weld made by lapping two metals before hammering.
- Larboard.**—In navigation, the left-hand or port side. Opposed to *starboard* or right-hand side.
- Latch.**—A sort of self-locking device which may be disengaged usually without the use of a key.
- Lattice-girder.**—A girder with web consisting of diagonal pieces crossing like latticework.
- Lead** (pronounced lead).—Opposed to lag. In earthwork, the distance from c. of g. of cut to c. of g. of fill. The pay-lead may be less than this distance. In steam-engines, the advance of a valve or valves so that the steam is admitted in front of the piston, or allowed to escape behind it, before the end of the stroke.
- Leader.**—In mining, the leading vein. A pipe leading from the roof to conduct rain-water. The principal wheel in a mechanism, and giving motion to the *follower*.
- Leading-block.**—A block for simply keeping a rope in a certain lateral position, without transmitting any of its power.
- Leading-wheel.**—In a locomotive, one of the smaller wheels ahead of the driving-wheels.
- Leaf.**—A tooth of a small pinion.
- Leaf-bridge.**—A small draw with leaves swinging vertically.
- Leaf-valve = flap-valve = clack-valve.**—A hinged or pivoted valve in a pumping engine.
- Lean-to.**—A roof or building whose rafters pitch against another structure.
- Ledge.**—A shelf or something projecting, as a small horizontal molding, or the side of a rebate against which a window or door is stopped.
- Lewis.**—A contrivance for securing a hold in a vertical wedge-shaped hole in a block of stone, for hoisting it; consists of two side pieces of metal wedging a center piece (called lewis-bolt) firmly and to which the hoisting tackle is attached.
- Lewis-bolt.**—A wedge-shaped bolt fastened in a hole drilled in a stone, by pouring lead around it or by inserting metal wedges. If used for lifting the stones it is provided with an eye and is an eye-bolt.
- Lewis-hole.**—The hole drilled in a stone for a lewis.
- Lift.**—The rise in a canal-lock. The vertical distance from one level to another in a mine, or a set of pumps. A machine for lifting.
- Lift-bridge.**—A bridge which is raised to accommodate cross-traffic, as in a canal.
- Lift-pump.**—Opposed to *force-pump*.
- Lift-wall.**—The cross-wall of a canal-lock chamber.
- Lighter.**—A water-craft or barge used for unloading or loading cargoes of vessels while anchored in the harbor.
- Light-ship.**—A vessel at anchor used as a sort of light-house.
- Linch-hoop.**—A ring on a carriage-axle fastened by a linch-pin.
- Linch-pin.**—A pin on the end of a carriage-axle to hold the wheel on.
- Link.**—One of the rings or separate pieces of a chain. In surveying, the

- hundredth part of a chain; equal to 12 inches in an engineer's chain, or 7.92 inches in a surveyor's or Gunter's chain. In a steam-engine, the links or parts forming the link-motion.
- Link-lever.**—In a steam-engine, the reversing lever controlling the link of the link-motion valve-gear.
- Link-motion.**—In a steam-engine, a system of levers for controlling the valves in starting and reversing the engine, and for cut-off.
- Lintel.**—A horizontal beam for supporting a wall over a door or window or other similar opening of moderate span; termed a *breast-summer* when the opening is large.
- List.**—In architecture, a square molding, fillet or *listel*. A narrow strip from the edge of a board. The first or thin coat of tin on iron plates, to be followed by a heavier coat. The tipping of a vessel due to unequal loading.
- Liter.**—A unit of capacity, equal to 1.056 U. S. quarts.
- Litharge.**—A protoxide of lead (*Pb O*), used in the composition of flint-glass, varnishes and drying-oils.
- Load.**—In mechanics, the pressure upon any part of a structure.
- Load-line.**—The line around a vessel to show the allowable load: when she sinks in the water to that mark.
- Loam.**—In foundry-work, a mixture of clay, sand, sawdust, etc., used in making the molds for castings of iron and brass.
- Lock.**—A device for fastening doors, gates, etc.; composed of a bolt, wards (for guarding against the entrance of a key not of the right pattern), tumbler (to hold the bolt in position and render the operation of a wrong key difficult), and a spring. A mortise-lock is one concealed, as in a house-door. An enclosure or chamber in a canal with gates at each end, for allowing boats to pass from one level to another.
- Lock-nut = check-nut = jam-nut = pinch-nut.**—A nut screwed down on another to keep it in place.
- Log-beam.**—A traveling frame for supporting and feeding logs to the saw, in a saw-mill.
- Log-scale.**—A table showing the quantity of lumber, in B. M., procurable from a log when sawed; the length of log and its diam. beneath the bark being given.
- Louwer = louvre.**—A long window, usually at tops of roofs of shops, depots, etc., with the opening traversed with broad slats sloping downward and outward, like the slats of a window-blind, to provide for ventilation and exclude rain.
- Lozenge.**—A plane figure shaped like a rhomb or diamond, having four equal sides with two acute and two obtuse angles. In art, the lozenge pattern is a pattern with diamond-shaped figures, or lines meeting or crossing each other at regular intervals but not at right angle.
- Lug.**—A short flange or projecting piece on anything, as in a casting, by or to which something is fastened or supported or kept rigid, etc.
- Lug-bolt = strap-bolt.**—A bolt terminating in a long flat extension or bar which takes the place of a head; made by welding a flat bar to a common bolt. The bar often contains holes for bolts or screws to fasten to timber. There are various forms.
- Lumber-car.**—A railroad car for carrying lumber; usually 34 ft. long.
- Lumber-kiln.**—An artificially warmed chamber in which lumber is placed to deprive it of its moisture. The heat is often furnished by coils of steam-pipes, and the moisture in the air, from the wood, is condensed, as on cold-water pipes hung in the room, and the drippings conducted out of the chamber. The green lumber may be run into a kiln on cars and remain on them until dried.
- Machine-bolt.**—A threaded bolt with a square or hexagonal head.
- Machine-tool = engine-tool.**—A machine operated by power (water or steam, etc.) for performing operations which may be, or which formerly were, accomplished by the use of hand-tools, as drilling, planing, etc.
- Magnet, Electro.**—A magnet produced by a passage of an electric current through a coil of insulated wire surrounding a core of magnetizable material. The directions of the currents required to produce N and S poles, respectively, are shown in the accompanying illustrations. A magnetizing coil is called a helix or solenoid.
-
- Main.**—The chief pipe-line in a system of waterworks; any pipe-line in a

distributing system tapped for domestic supply. Water-main. Similarly with gas, as gas-main.

Main-link.—The bar that connects the piston-rod with the beam of the engine.

Malleability.—The property of being malleable, i. e., of being shaped, by hammering or rolling, without fracture, as malleable brass or iron.

Mallet.—A wooden hammer or small beetle used by stonecutters, carpenters, etc.

Mandrel.—A bar or spindle inserted in any work to hold it or shape it, as in a lathe. The spindle of a turning lathe; the arbor or axis of any tool, as a circular saw or cutter; a rod for shaping the inside or hollow of anything, as the plug-core of a metal casting.

Mandrel-collar.—A collar formed on the mandrel of a lathe, against which the chucks abut.

Mandrel-lathe.—A lathe for turning long hollow work; the material is clamped by a chuck on the end of the mandrel.

Manhole.—An opening in a sewer, culvert, drain, cesspool, steam-boiler, tank, etc., through which a man may enter for the purpose of inspecting, repairing, cleaning, etc.

Marble-saw.—One or more thin iron blades, set in a frame and reciprocated on a block of marble to be sawed, the kerfs being fed with sand and water.

Mark.—A German coin of the value of \$0.238.

Marking-gage.—A small graduated rod with a steel point on one end for scratching a line on the wood, and with an adjustable block for gaging the line from the edge of the board.

Mari-brick—mari-stock.—A superior brick for the fronts of buildings and for arches.

Marlinespike.—A pointed iron tool used by riggers to separate the strands of rope in splicing.

Marsh-gas.—Carburetted hydrogen; a constituent of *fire-damp*.

Masonry.—Generally defined as anything constructed of the materials used by masons, as stonework, brickwork, tilework, etc.; but now it is considered as including concrete, cyclopean masonry (which see) or rubble-concrete masonry, and reinforced-concrete masonry. Dry masonry comprises masonry built without mortar. See subject of Masonry, Section 25.

Mass.—The weight of a body divided by the gravity acceleration at the place where the weight is measured.

Mass-center—center of mass.—A point through which if a plane is passed in any direction, the sum of the products of all the minute masses or particles on one side of the plane each multiplied by its respective distance from that plane, will be equal to the sum of similar products of particles and distances on the other side of the plane.

Mass, Magnetic.—A quantity of magnetism which at unit distance produces an action equal to unit force.

Master-wheel.—The chief wheel or the driving-wheel of a mechanism or machine.

Mat-boat—matting-boat.—A sort of framework on scows for making and launching mats to protect river-banks from scour.

Match-board.—A board with a tongue on one edge and a groove on the other for constructing partitions, floors, etc., of match-boarding or matched-boarding.

Match-plane.—One or two planes for preparing the edges of matched-boards.

Mathook.—A long pole with an iron hook used in the construction of mats for river-bank protection.

Mattock.—A kind of pick for digging, but having the edges broad instead of pointed.

Maul.—A heavy wooden hammer.

Maximum.—The greatest value or upper limit. The greatest of several maxima is termed the *absolute maximum*, or *maximum maximorum*. Opposed to *minimum*.

Mean.—An intermediate value in a series, from which it is derived. *Arithmetical mean* is the sum of n quantities divided by n . *Geometrical mean* is the square root of the product of two numbers. *Mean error* is the quadratic mean of the errors of observation.

Meander.—A series of transit or compass lines in a survey, with distances, angles or bearings, and perhaps levels.

- Meander-line.**—A part or the whole of a *meander*.
- Mean proportional.**—Geometrical-mean. See *Mean*.
- Megohm.**—A large measure of electrical resistance: one million ohms.
- Melt.**—The charge of metal in a cupola or pot, for melting or after being melted.
- Melting-pot.**—A pot for melting. A crucible.
- Member.**—A subordinate part of a structure, as a post or a diagonal of a truss.
- Mercury-furnace.**—A furnace for roasting cinnabar so the mercurial fumes will arise, to be condensed in a series of vessels.
- Meridian.**—Noon. A north and south line, on the earth, or on the celestial sphere.
- Meter.**—A unit of length; 39.37 ins. by U. S. law.
- Meter, Watt.**—An instrument for measuring current flow in watts (volt-amperes).
- Mica.**—A mineral substance employed as an insulator, as for instance of commutator bars.
- Micro.**—The one-millionth.
- Micrometer.**—An instrument for measuring exceedingly small lengths and angles.
- Mil.**—The unit of length equal to the $\frac{1}{1000}$ of an inch, or .001 inch, used in measuring the diameter of wires.
- Mil, Circular.**—A unit of area employed in measuring the areas of cross-sections of wires; equal to 0.7854 square mil. One circular mil = .00000785 square inch.
- Mill-furnace.**—A furnace for re-heating metals to be rolled into shapes or welded under the hammer.
- Milligram.**—One thousandth of a gram, equal to about $\frac{1}{65}$ of a grain.
- Milliliter.**—One thousandth of a liter, equal to about 0.061 cu. in.
- Millimeter.**—One thousandth of a meter, equal to 0.03937 inch.
- Mil, Square.**—A unit of area employed in measuring the areas of cross-sections of wires; equal to $.001 \times .001 = .000001$ square inch. One square mil = 1.2732 circular mil.
- Miner's Inch.**—See page 1313.
- Minimum.**—The smallest or least quantity. Pl., *minima*.
- Miter = mitre = miter-joint.**—A joint whose line makes an angle of 45° with each of the two pieces joined together at right angle. A *bevel-joint* is one whose line makes any angle greater or less than 45° with two pieces joined together at any angle.
- Miter-sill.**—A raised sill against which the bottom of the canal-lock gates shut on the floor of the lock-bay.
- Miter-wheel.**—One of two wheels of a mechanism whose teeth engage, the planes of the wheels being at right-angle with each other.
- Modulus = coefficient.**—A constant or positive number used as a measure of some function, as the modulus or coefficient of elasticity of a material, the modulus depending upon the material and the method of testing, etc.
- Moment.**—The product of a force into its shortest leverage distance. See page 305.
- Monkey = ram.**—The hammer of a pile driver.
- Monkey-engine.**—A pile-driver.
- Monkey-wrench.**—A common wrench, with one jaw adjustable by a screw, for screwing on nuts, etc.
- Monument.**—An artificial landmark used by surveyors to fix a point or a corner on an instrument- or a property line. Granite monuments, 6" square at top and 3 to 5 ft. long are serviceable. Small gas-pipes are frequently used in suburban districts for semi-permanent work.
- Mooring.**—That to which a ship or anything is secured.
- Mooring-swivel = mooring-shackle.**—A swivel used to connect two anchor-chains together just above the water, say at the forward end of the ship, when both anchors are out.
- Mortise.**—A part of a mortise-and-tenon joint; the hole in timber to receive the tenon, and made by a carpenter's mortise-chisel.
- Motor, Electric.**—A device for transforming electric power into mechanical power. Electric motors are specially designed for continuous current or for alternating current or for rotating current.
- M-roof.**—A double pitch-roof forming an inverted W.
- Muck-bar.**—An iron bar which has been passed through the muck-rolls only, of a rolling-mill.

- Muck-rolls.**—The first pair of rolls for rolling iron; the bars are finished by passing them through the *merchant train* or *puddle-bar train* of rolls.
- Mullion.**—A vertical division between the lights of windows, screens, etc.
- Munnion.**—In ship-building, a vertical division or piece between the panels of framed bulkheads.
- Muntin**—**munting.**—The central vertical piece dividing the panels of a door.
- Mutule.**—A flat block projecting under the carona of the Doric cornice; a sort of modillion.

N.

- Nadir.**—The point in the heavens vertically below any station on the earth. Opposed to *zenith*, which is a point vertically above.
- Nail-plate.**—A metal plate of the proper thickness for cutting up into nails.
- Naphtha.**—A colorless liquid distilled from petroleum. Largely used in the manufacture of illuminating gas, and for light and power in general.
- Nave.**—The long, main, central interior part of a church, including the central aisle. The hub of a wheel.
- Nave-box.**—The metallic ring inserted in the nave or hub of a wheel, to reduce the wear.
- Needle-beam.**—The floor-beam of a bridge. A transverse bolster placed beneath the sills of a car and between the bolsters.
- Nest.**—A group of parallel steel rollers in a frame and used at the expansion end of a truss. A connected series of pulleys or cog-wheels.
- Net-masonry.**—Masonry with joints like the meshes of a net.
- Neutral feeder.**—The feeder that is connected with the neutral or intermediate terminal of the dynamos in a three-wire system of distribution.
- Newel.**—An upright pillar from which the steps of a winding stair radiate; or the large ornamental post supporting the hand-rail at the head or foot of a flight of stairs; or a round pillar at the end of the wing-wall of a bridge. Sometimes called *newel-post*.
- Niche.**—A nook or recess in a wall for a statue.
- Nippers.**—A tool like pincers or tongs for grasping hold of small objects; sometimes with cutting edges for cutting wire and small pieces of metal. In engineering, two toothed jaws attached to gearing, for cutting off piles under water.
- Non-Conductors.**—Substances that offer so great resistance to the passage of an electric current through their mass as to practically exclude a discharge passing through them. Insulators.
- Normal.**—Perpendicular; at right-angle to the tangent to a curve at the point of tangency. According to the rule or right principle.
- Nose-piece.**—The nozzle of a hose.
- Nose-pipe.**—The nozzle of a blast-pipe inside the twyer of a blast-furnace.
- Nosing.**—The projecting edge of a molding, or of a tread or step of a stair.
- Nullied-work.**—In wood-turning, pieces or wood turned to form a series of connected beads or knobs, as in the rounds of cheap chairs and bedsteads.
- Nut.**—A sort of adjustable head to a screw-bolt. A short piece of iron with a central female screw to fit the screw of a bolt.
- Nut-coal.**—Chestnut-coal.
- Nut-lock**—**nut-fastening**—**jam-nut.**—A device for fastening the nut on a bolt so it will not work loose.
- Nut-machine.**—A machine for making (cutting, stamping and swaging) iron nuts from a heated bar fed to it.

O.

- Oakum.**—The coarse part of hemp or flax, removed in combing or hackling.
- Obelisk.**—A large rectangular, monumental shaft, tapering from the base upward, and with a pointed top. Many abound in Egypt. One in Central Park, New York City, near Metropolitan Museum of Art.
- Octastyle.**—An architectural feature of a portico with eight columns in front.
- Odometer.**—An instrument to be attached to a wheeled vehicle for measuring distances traveled; useful in preliminary surveys in connection with the compass, and especially for making maps of country roads.
- Ogee**—**O. G.**—A reverse curve, as in a sectional outline of some molding, or of a cast-iron washer; hence *ogee washer* or *O. G. washer*. A cyma.

- Ohm.**—The unit of electric resistance. It really expresses a velocity, namely, 1,000,000,000 centimeters per second. Thus, the formula for resistance in electro-magnetic units (see Units, Electro-Magnetic, Dimensions of) is $R = \frac{E}{C} = \frac{L}{T} = \frac{\text{Length}}{\text{Time}} = \text{Velocity}$.
- Ohm, British Board of Trade.**—The resistance of a column of mercury 106.3 centimeters in length and one square millimeter area of cross-section at 0° C.
- Ohm, British Association.**—The resistance of a column of mercury 104.9 centimeters in length and one square millimeter area of cross-section at 0° C. (Not used.)
- Ohm, Legal.**—The resistance of a column of mercury 106 centimeters in length and one square millimeter area of cross-section at 0° C. or 32° F. (Never legalized.) One ohm = 1.00112 B. A. Units.
- Ohm, Standard.**—A length of wire having a resistance of the value of the true or legal ohm, employed in standardizing resistance coils.
- Ohmmeter.**—A commercial galvanometer for measuring ohmic resistance.
- Oil-cellar.**—A metal box containing oil for oiling the crank-pin, and attached to the under side of the strap of the connecting-rod of the engine.
- Oil-pump.**—A pump for discharging oil upon a journal.
- Oil-tempering.**—The tempering of steel with oil (not water).
- Oil-well.**—A boring made for petroleum.
- O. K.**—Correct; all right. (Oll Korrekt.)
- Opaque.**—Dark; shady; obscure; not transparent; impervious to light.
- Open-hearth furnace.**—A furnace used in making steel by the Siemens-Martin process, with certain late improvements.
- Openwork = open-cast.**—Relates to mining or quarrying done in the open air, i. e., not covered.
- Ordinate.**—An offset from a base line to any given point. In analytic geometry, one of the coordinates locating a point on a curve from two co-ordinate axes. See *Abscissa*.
- Oscillator.**—Anything which has or produces a rapid reciprocating motion within a limited range of distance, as a power-hammer, the shuttle of a sewing-machine, the piston of a steam-engine, etc.
- Osier.**—A specie of willow, much used in river-bank protection.
- Outfall.**—The discharge end of a river, sewer, culvert, drain, etc.
- Outfall-sewer.**—That portion of a large sewer which receives the sewage from one or more districts and discharges it, as into a river or ocean.
- Out of wind.**—Not winding; straight. Specifications calling for timber out of wind, mean that the faces shall not be warped.
- Overshot-wheel.**—A mill-wheel with blades or buckets around the periphery, and designed to operate by water shot over the top on the descent.
- Ovolo = quarter-round.**—A convex molding forming a quarter of a circle. In Greek architecture the moldings are a quarter-ellipse, like an egg, instead of a quadrant of a circle.
- Ozone.**—Modified oxygen; its density is one and one-half times that of oxygen. It exists in cold regions and in country districts. Can be produced by an electric spark passing through air or through oxygen. It is a great purifier and bleacher.

P.

- Packing.**—In machinery, material stuffed around moving parts, as in a stuffing-box, to prevent leakage of steam, water, etc.
- Packing-ring.**—A metal- or rubber-ring used as seat for a coupling-valve of a car, to make an air-tight joint.
- Pack-train.**—Pack-animals with their loads.
- Pallet-molding.**—In brick-making, a process in which the mold is sanded after each using.
- Panel.**—Any area slightly sunk, or raised, or more or less distinct, as the panel of a door. The panel of a truss is the vertical area embraced between the chord-joints or floor-beams; the length of a panel times the number of panels is equal to the span.
- Panel-strip.**—A narrow strip on the edge of a panel or between two panels.
- Pantile = pan-tile.**—A tile with surfaces curved transversely, and overlapping and underlapping adjacent tiles, thus:
and laid on a roof shingle-fashion.

- Pantograph.**—A lever-like instrument with arms for reproducing a sketch to the same scale or to another scale.
- Paraffin = paraffine.**—A substance obtained by the dry distillation of wood, wax, peat, bituminous coal, etc.
- Parallax.**—In an object glass, an apparent lateral movement of the cross-hairs as the eye changes position: occurs when the hairs are not co-incident with the focal plane.
- Parapet.**—A top wall of a masonry structure, forming a sort of breastwork. The parapet of an abutment is the long transverse wall on the back edge of the coping, rising nearly to sub-grade, to protect the bridge-seat from the earth embankment of the roadbed.
- Parcel.**—To wind anything, as a rope, with strips of canvas.
- Parget.**—To cover, gloss over, or smooth over, the surface of anything with parget or plaster.
- Parthenon.**—The temple of Athene Parthenos, at Athens.
- Party-wall.**—A building-wall centrally located on a property-line or party-line, for joint use; it may belong to one or to both property owners.
- Pasometer.**—A watch-like pocket-odometer for registering walking- or running distance.
- Patent hammer.**—A hammer for dressing stone, and having sharp knife-like ridges on the face.
- Pattern.**—An original, or model, or mold for anything. Patterns for castings, as chord-blocks of Howe trusses and combination trusses, are made of wood, and due allowance must be made for shrinkage of metal.
- Pawl.**—A short iron bar or ratchet to engage the saw-like teeth of a ratchet-wheel to prevent a windlass or capstan from turning back.
- Pay.**—On a ship, to cover with a coat of tar or pitch, as a seam, or a rope.
- Pay out.**—To slacken rope, as a cable or main sheet.
- Peak.**—The upper corner of a sail. *Forepeak* is the forward extremity of a ship's hold, as opposed to *after-peak*. Peak load means maximum load.
- Peat-charcoal.**—Charcoal made by carbonizing peat.
- Pediment.**—The triangular front-end of a building included between the portico and the sloping edges of the roof.
- Peen = pean.**—The end of the head of a peen hammer (pean-hammer).
- Peen-hammer.**—A pean-hammer, or hammer with two opposite cutting edges for dressing stone. A hammer with a chisel edge, used for straightening iron plates.
- Pendentive.**—In architecture, a triangular segment of a hemispherical dome rising from four supports formed by two intersecting arches.
- Penstock.**—A channel or conduit supplying water from the race to the gate, through which the water flows to the wheel of the mill or power-plant.
- Percussion-cap.**—A small metal cap or cup containing fulminating (detonating or exploding) powder, for exploding dynamite or gunpowder.
- Perihelion.**—A point in the orbit of a planet or comet in which it is nearest to the sun. Opposed to *aphelion*, in which it is farthest from the sun.
- Perimeter.**—Circumference or outer boundary.
- Periodicity.**—The rate of change in the alternations or pulsations of an electric current.
- Periphery.**—Circumference of a circle; arc.
- Peristyle.**—In architecture, columns arranged around an enclosure, or any part of same, as a court, or cloister.
- Permeability, Magnetic.**—Conductibility for lines of magnetic forces. The ratio existing between the magnetization produced, and the magnetizing force producing it. Permeability, $M = \frac{B}{H}$.
- Perron.**—In architecture, a flight of steps to a building in which the principal floor is raised considerably above the ground level.
- Pestle.**—One of the vertical moving bars in a stamp-mill for crushing ore.
- Petroleum-still.**—A still for separating the hydro-carbons, in the order of their volatility, from crude petroleum.
- Phase, Angle of Difference of, between Alternating Currents of Same Period.**—The angle which measures the shifting of phase of a simple periodic current with respect to another due to lag or other cause.
- Phase, Shifting of, of Alternating Current.**—A change in phase of current due to magnetic lag or other causes.
- Photometer.**—An instrument for measuring the intensity of light, or comparing one with another.

- Pick.**—A pointed instrument with a handle used in loosening any material by vertical swinging. The common pick for loosening earth. The stone-pick.
- Pickaxe**—**pickaxe.**—A sort of combination of pick and mattock: with one end pointed and the other flat.
- Pier.**—One of the supports of a bridge; generally, one of the central supports of two or more spans, the end supports being termed *abutments*. The solid support from which two or more arches spring. The support of a wall, between openings. A structure built out into the water, to support something, as freight, traffic, warehouses, etc. Usually conveys the ideas of *length* and *support*.
- Pierre perdue.**—Masses of stone thrown into the water to serve as a sub-foundation, as for a breakwater.
- Pig.**—A cast of metal in compact form, as iron from a blast-furnace.
- Pigment.**—Any substance used by painters to give the desired color.
- Pilaster.**—A sort of quarter- or half-pillar projecting from the face of a wall, and having the proportional parts of capital and base.
- Pile.**—Any long piece driven or planted in the ground to serve as a sub-foundation. May be of wood, iron, concrete, reinforced-concrete, etc.
- Pile-hoop.**—An iron ring driven over the head of a pile to prevent it from splitting, in driving.
- Pile-plank.**—Planks driven into the ground like piles, as the sheet-piling of a coffer-dam.
- Pile-shoe.**—An iron point fitted to the lower end of a pile so it will penetrate more easily and not burr at the end.
- Pillar.**—A column.
- Pillow-block**—**plumber-block.**—The metal case or support for the end of a revolving shaft or journal.
- Pin, Insulator.**—A bolt by means of which an insulator is attached to the telegraphic support or arm.
- Pinch-bar**—**pinching-bar.**—An iron bar with a small lever-like snout at the foot, for working heavy masses sideways.
- Pinion.**—A small cog-wheel or gear-wheel geared to a larger one, and usually *giving* it motion.
- Pinnacle.**—A relatively small structure rising from the roof or walls of a larger one.
- Pin, Switch.**—A metallic pin or plug provided for insertion in a telegraphic switchboard.
- Pin-switch.**—An electrical switchboard by which connections are made by means of pins inserted in holes between plates insulated from each other.
- Pintle.**—A pin or dowel or long bolt upon which anything turns or revolves, as the cylindrical pins on which a blind or a rudder swings, the bolt on which the forward axle of a carriage swings under the body, etc.
- Pipe-coupling.**—A sort of sleeve which screws on the ends of two abutting pipes.
- Pipe-cutter.**—A sort of chisel-tool for cutting iron pipes by forcing it down on the pipe and around it.
- Pipe-line.**—A pipe-conduit.
- Pipe-tongs.**—A pair of tongs, one projection being sharp for pushing and the other one hooked for pulling, used in screwing pipe together, or into their couplings.
- Piston.**—A movable piece operated reciprocally by the steam in the cylinder of an engine; consists of the piston-head which fits the inside diameter of the cylinder, and the piston-rod which connects with the mechanism outside.
- Pitch.**—Inclination. In mechanics, the distance center to center (c. to c., or c. - c.) of two adjacent teeth of a cog-wheel, or of rivets when the measurement is along some base line, or of the threads of a screw, etc. The residuum of tar. The sap from the bark of pines.
- Pitch-board.**—A guide or pattern for carpenters in framing the strings of stairs, the right-angled notches for the treads and risers.
- Pitch-circle**—**pitch-line.**—In toothed-wheels, a circle intersecting all the teeth near the middle of their length, and which is tangent to a similar circle of a wheel geared to it; outlines the theoretical size of a toothed-wheel.
- Pitch-wheel.**—One of two toothed-wheels geared together.
- Pitman.**—A connecting-rod between a rotary and a reciprocating part.
- Pit-saw.**—A large saw operated by two men one of whom is below in the "pit."

- Pivot**.—That upon which something turns, as the center-pin or pivot-pin of a center-bearing drawbridge or turntable.
- Place-brick** = **sandel** = **samel-brick**.—In brickmaking, a soft brick, insufficiently burned.
- Planimeter**.—An instrument for measuring the plane area of any object or drawing of any irregular outline; it can be adjusted to the scale of the drawing. It is an integrator and is mathematically correct.
- Planish**.—To make smooth or polish. A *planisher* or flat-headed tool is used by tinnners; a *planishing-hammer* is used by metal workers, also a *planishing-roller*.
- Plant**.—Machinery, tools, and general outfit used in any mechanical operation or construction work, etc.
- Platband**.—A wide fillet. A flat molding. A lintel formed with voussoirs but with intrados horizontal, as an arch with infinite radius.
- Plate, Arrester, of Lightning Protector**.—That plate of a lightning protector which is directly connected with the circuit to be protected, as distinguished from the plate that is connected with the ground.
- Plate-girder**.—A girder with a web composed of steel plate.
- Plate, Ground, of Lightning Arrester**.—That plate of a comb lightning arrester which is connected with the earth or ground.
- Pliers**.—Small pinchers with long jaws for handling and bending small pieces of metal.
- Plinth**.—The flat square member at the base of a column.
- Plug**.—A piece to stop a hole. A cast-iron cap leaded in the end of a cast-iron water main. A cap screwed into the end of a pipe.
- Plug and feathers**.—An iron wedge or *plug* inserted in one of a series of holes in a stone, and between two semi-cylindrical pieces of iron called *feathers*, all the holes being similarly treated, in order to split the stone on the line of the holes, by striking the plugs with a sledge-hammer.
- Plumb**.—Vertical, as in the direction of gravity.
- Plumb-bob** = **plumb**.—A top-shaped metallic instrument, with the lower end pointed, suspended by a cord or plumb-line and used in surveying, carpentry, mason-work, etc., to obtain vertical lines. There are various kinds and shapes, suited to different classes of work.
- Plumber-block**.—See *pillow-block*.
- Plumb-joint**.—A soldered lap-joint, the edges of the metal not being bent or seamed.
- Plumb-level** = **pendulum-level**.—A board with a line perpendicular to its edge, used in connection with a plumb for obtaining levels.
- Plumb-rule**.—A narrow board with parallel edges and with a straight line drawn through the middle, used in connection with a plumb, for obtaining verticals, in bricklaying, carpentry, etc.
- Plummer-block** = **plumber-block** = **pillow-block**.—See *Pillow-block*.
- Plummet**.—A plumb or plumb-bob used by carpenters, masons, etc.
- Plummet-level** = **masons'-level**.—Similar to *plumb-level*, preceding.
- Plunger**.—A solid piston, as that of a Cornish pump; one without a valve.
- Pockets, Armature**.—Spaces provided in an armature for the reception of the armature coils.
- Point**.—A pointed chisel for dressing stone. To point is to dress masonry with a point; or to finish the outer joints with mortar.
- Pole-plate**.—A small wall-plate resting on the ends of the tie-beams of a roof, for supporting the lower ends of the common- or jack-rafters.
- Polygon**.—A figure with numerous sides and angles.
- Pontoon**.—One of a series of flat-bottomed boats or floating structures, used in the construction of a temporary bridge across a stream, or for support of a pipe-line in hydraulic dredging, etc.
- Pontoon-bridge**.—A bridge or roadway supported on pontoons.
- Port**.—One of two passages leading from the steam-chest to the inside of the cylinder of an engine, above and below the piston, and controlled by valves so that the steam enters and exhausts at the proper time.
- Portal**.—A door, gate, opening, entrance, etc., to a passage, as to a tunnel or cathedral.
- Post**.—A compression member connecting the two chords of a truss. An *end-post*, or an *intermediate-post*, of a truss.
- Potential, Alternating**.—A potential, the sign or direction of which is alternately changing from positive to negative.
- Potential, Constant**.—A potential which remains constant under all conditions.
- Potential, Difference of**.—A term employed to denote that portion of the

- electromotive force which exists between any two points in a circuit. In a battery or dynamo it is the total E. M. F. that is available. It may be measured by "method of weighing," by "use of electrometers" or by "use of galvanometers."
- Potential, Drop of.**—Fall of potential.
- Potential, Electric.**—The power of doing electric work. Comparing with flow of water, it is the "pressure" or "head."
- Power.**—The rate of work. (Energy is capacity for work.)
- Power, Horse, Electric.**—Such a rate of doing electric work as is equal to 746 watts or 746 volt-coulombs per second.
- Pressure.**—A force in equilibrium, i. e., opposed by an equal and opposite force. Pressure is usually stated in lbs. per sq. in. or in lbs. per sq. ft. The pressure on bridge masonry, under the pedestals, is usually limited to about 250 lbs per sq. in., depending upon the quantity of the stone, etc.
- Prime.**—First of anything, as the *prime* coat, in painting. To prime means to charge, as to pour water into a pump-tube to start suction.
- Principal.**—[This word may be used in various branches of mechanics to denote the *chief* or *main* of anything where there are also similar but subordinate parts, as *principal axis*, *principal rafter*, etc.]
- Pronaos.**—An open vestibule or portico.
- Pro rata.**—In proportion.
- Proscenium.**—That part of a theater between the drop-scene or curtain and the orchestra. Thus we have the proscenium-arch and the proscenium-box.
- Pro tem.**—*pro tempore*.—Temporary; for the time being.
- Prow.**—The bow of a vessel.
- Prox.**—*proximo*.—In or of the next or coming month.
- Puddle-bar.**—Bar-iron from the puddle-rolls of a mill.
- Puddle-rolls.**—Grooved iron-rollers for rolling iron as it comes from the puddling-furnace and forge.
- Puddling.**—The process of ramming plastic clay into a structure to prevent leakage, as in making the puddle-core of an earth-dam. Also, the converting of pig-iron (cast-iron) into wrought-iron in a puddling-furnace (reverberatory furnace).
- Pugging.**—Mixing clay for bricks. The *deadening* of sound through a floor or partition by interposing some composition or construction; the construction itself.
- Pug-mill.**—A machine for mixing and tempering clay for bricks, etc.
- Pug-piling.**—Dovetailed piling, the piles being mortised into one another with a dovetailed-joint.
- Pulley.**—A mechanism consisting of a *shell* (block) containing one or more *grooved wheels* (sheaves) over which a rope runs for hoisting. One or more pulleys together with the hoisting rope comprise what is called a *tackle*. Also, a sort of drum over which a belt or cable or rope runs, without winding around it.
- Pulsometer.**—A kind of pump without a piston; operates by steam-condensation and partial vacuum.
- Punt.**—A small boat, square-ended and with a flat bottom.
- Puppet.**—The head- or tail-stock of a lathe.
- Puppet-valve.**—A valve which lifts bodily from its seat when open.
- Purlin**—*purline*.—One of a series of parallel timbers laid horizontally on the main or principal rafters of a roof to support the common or jack-rafters. Pl.—Horizontal shapes, as tees, for supporting any roofing material, as tiling.
- Put-log.**—One of several pieces of timber used in forming the floor of a scaffold; one end being inserted into a *put-hole* in the side of the building and the other end supported by a horizontal string secured to poles erected from the ground.
- Putty.**—A mixture of soft carbonate of lime or whiting, with linseed-oil.
- Pyx.**—The metallic box in which the nautical compass-card is suspended.

Q.

- Quadrangle.**—A court, square or rectangular, nearly or quite surrounded by buildings.
- Quadratic.**—In algebra, an equation in which the highest power of the unknown quantity is the second power.

- Quadrature of the circle.**—The *exact* determination in square measure of the area of a circle. Never been solved exactly, either arithmetically or geometrically, by any limited expression.
- Quantity, Unit of Electric.**—A definite amount or quantity of electricity called the coulomb.
- Quay.**—A landing place for vessels; a wharf.
- Queen-post truss.**—A truss with two upright intermediate posts meeting the end-posts at their tops. Used as roof-trusses. The posts are called queen-posts. Queen-post stays are the long rods running below the two queen-posts which support the body of the car between the trucks.
- Quirked-molding—quick-molding.**—A form of molding having an abrupt re-entrant angle at its extreme projection.
- Quoin.**—Blocks of stone at the corners of buildings and projecting somewhat from the face of the wall; the subordinate corners of the stones being chamfered off, usually. The recess into which the heel-post of a lock-gate is fitted.
- Quoin-post.**—The heel-post of a lock-gate, on which the latter turns.

R.

- Rabbet.**—A groove, channel, halving or other cut along the edge of a board to fit a corresponding cut on another board to fit it. A joint so formed by two boards is called a *rabbet-joint*. Rabbet-saws and rabbet-planes are used in preparing the cuts or grooves.
- Race.**—*Head-race* is a channel, canal or watercourse from a dam to a water-wheel; *tail-race* is such a water-course after it leaves the wheel.
- Rack.**—One or more long metal bars fitted end to end, forming either a straight or a circular piece, and having teeth on one of its sides or edges to engage or work into the teeth of a wheel, pinion or screw. If the rack is curved it is a *segment-rack*; if it is a circle it is called a *circular-rack* and is usually composed of segments, as the cast-iron rack in the turntable of a drawbridge.
- Rack-and-pinion.**—A small cog-wheel or pinion geared to a rack.
- Rack-and-pinion-jack.**—A lifting-jack operated by a straight rack and pinion.
- Rack-and-worm.**—A rack geared to a worm or screw instead of to a pinion.
- Rack-railway.**—A railway operated by a gear-wheel of the car or locomotive engaging the teeth of a rack-rail—a rail laid along the track and provided with teeth or cogs. Used on inclined planes, as up the sides of mountains.
- Rack-saw.**—A saw with wide teeth.
- Raft-dog.**—An iron bar with ends pointed and bent at right-angle with body of bar; used for securing logs together in a raft.
- Rag-bolt—barb-bolt—sprig-bolt.**—A sort of jag-spike, or iron spike or pin with its shank barbed so as to make it difficult to withdraw after being driven.
- Rag-wheel—chain-wheel—sprocket-wheel.**—A wheel with teeth on the rim to engage the links of a chain.
- Rail-bender—rail-bending machine.**—A machine for applying lateral pressure on a rail supported against a bearer, for the purpose of straightening or curving it.
- Rail-saw.**—A portable saw for sawing steel rails.
- Ram.**—The hammer of a pile-driver. The steel hammer used in forming a bloom, in metal-working.
- Rammer.**—An instrument for ramming; thus, pavers' rammers, founders' rammers, gunners' rammers, etc.
- Random stone.**—Rip-rap; stone dumped but not evenly placed, as for slope protection or for the sub-foundation of a breakwater.
- Random stonework—random work.**—A masonry construction formed of stone laid in irregular courses.
- Rasp.**—A coarse file; various forms for the trades.
- Ratchet—ratchet and pawl.**—A bar or wheel furnished with teeth which engage the end of a pivoted bar or click when it tends to turn backward. Used for hoisting, etc. Hence, *ratchet-brace*, *ratchet-coupling*, *ratchet-drill*, *ratchet-jack*, *ratchet-lever*, *ratchet-wheel*, *ratchet-wrench*, etc.
- Ratio, Velocity.**—A ratio, in the nature of a velocity, that exists between the dimensions of the electro-static and the electro-magnetic units.
- Ratline—ratlin—ratling—rattling.**—One of the small horizontal ropes forming steps to the shrouds of a vessel, for going aloft.

Reamer.—A tool with sharp lateral edges or fluted sides for smoothing punched holes in plates of metal, or for enlarging them. They may be reamed tapered by using a reamer with tapered flutes.

Réaumur's scale.—A thermometer with the freezing-point zero, and the boiling-point 80. Superseded by the centigrade scale, 0 and 100, respectively.

Rebate = rabbet = rabate.—See *Rabbet*.

Reciprocal.—The reciprocal of a number is 1 divided by that number, the result being expressed usually in decimal form. Reciprocal motion is alternating motion.

Reconnaissance = reconnoissance.—A critical examination of a country or territory prior to the preliminary survey.

Reducer.—A short pipe of variable diameter for connecting two pipes of different diameters. Also called an *increaser*.

Reëntering-angle = reëntrant angle.—An angle or corner pointing inward.

Reflux.—Flowing back. A *reflux-valve* is one designed to prevent back-flow; a back-pressure valve.

Refraction.—Deflection or change of direction of rays of light; due to the rays passing through a medium of varying density, as the air, or from one medium to another, as air to water or water to air. Witness the blade of an oar in the water; it *seems* to bend at the surface. When rays pass into a denser medium they are refracted toward the perpendicular to the surface, and *vice versa*.

Refrigerating-machine.—A machine for absorbing heat or converting it into work, and hence producing cold.

Reluctance, Magnetic.—Magnetic resistance.

$$\text{Reluctance} = \frac{\text{The magneto-motive force}}{\text{The magnetic flux}}.$$

Replacing-switch.—A device for replacing rolling-stock on the track.

Resistance, Electric.—Resistance in ohms = $R = \frac{E}{C} = \frac{\text{Electromotive force}}{\text{Current}} = \frac{\text{Volts}}{\text{Amperes}}.$

Retaining-wall = retain-wall = revetment.—A (steep) wall (of masonry) built to prevent a bank of earth from sliding or washing away. A structure designed to resist lateral pressure of loose material, as earth. See Retaining Walls, Section 48.

Revetment.—See *Retaining-wall* above, but applies particularly to fortifications, the protection of river-banks, etc.

Revolution.—Turning through 360°, or a complete circle; a cycle.

Rheostat.—An adjustable resistance. A rheostat enables the current to be brought to a standard, i. e., to a fixed value, by adjusting the resistance.

Rheostat, Dynamo-Balancing.—An adjustable resistance whose range is sufficient to balance the current of one dynamo against another with which it is required to run in parallel.

Rheostat, Water.—A rheostat the resistance of which is obtained by means of a mass of water of fixed dimensions.

Rib.—One of the curved pieces of iron or timber, as of a dome, arch, vault, vessel, etc., to which the outer shell is secured.

Ridge.—The highest part of a roof; the line of meeting of the upper ends of the rafters.

Ridge-pole = ridge-piece = ridge-plate.—The timber or iron piece along the ridge of the roof into which the rafters are secured.

Right and left.—In the frame of structures, certain members are *rights* and their counterparts are *lefts*, some small details being on opposite sides of the members otherwise alike, as the end-posts of a bridge. In such a case it is necessary to make only one drawing and call it the *right*, accompanied by explanatory notes describing the *left*. Similarly, we have right-and-left spring-frogs, switches, door-locks, screws, etc.

Right bank of a river is the bank on the right-hand side in descending a stream.

Right solid.—A solid with axis perpendicular to base.

Rim-saw.—A saw with a central circular disk over which is fitted a central band of teeth lying in the plane of the disk.

Ring-bolt = eye-bolt.—See *Eye-bolt*.

Ring-chuck.—A chuck to a lathe fitted with a ring over the end.

- Ring-dog.**—Two iron dogs for driving into and hauling timber, and connected by a ring; called a *sling-dog* when connected by ropes or chains.
- Riparian.**—Marginal or bordering on, as relating to the shore of an ocean, a bay, or a stream.
- Riparian owner**—**riparian proprietor.**—One who has vested control in the soil to the thread of a stream or to some line in the water established by law.
- Riparian rights.**—The rights of a riparian owner, as fishing, ferriage, wharf or other construction, filling in, etc.
- Riprap**—**rip-rap.**—Broken stone loosely dumped; used for walls, foundation-beds, bank protection, etc.
- Rip-saw**—**ripping-saw.**—A saw used in sawing wood in the direction of the grain, by hand.
- Rising-main.**—The vertical column of pipe through which water is pumped from a mine.
- Rising-rod.**—The valve-rod of a Cornish pumping-engine.
- Riveting-machine.**—A power machine for driving and heading rivets; may be operated by steam, hydraulics, electricity, etc. Many are portable.
- Road-machine.**—A large scraper mounted on wheels and used for scraping, transporting and dumping earth; used in road-making, shaping and repairing.
- Road-plow.**—A strong plow for loosening earth, etc.
- Road-roller.**—A heavy roller for compacting the surfaces of roads; operated by steam-power usually.
- Road-scraper.**—A scraper for handling earth which is fairly loose or has previously been loosened.
- Roadstead**—**road.**—An unsheltered place where vessels can anchor; not a sheltered harbor.
- Roadway.**—The width of roadway in excavation or embankment is the width at sub-grade between edges of slopes.
- Rock-crusher.**—A machine for breaking rock into suitable sizes, as for concrete. A stone-breaker.
- Rock-drill.**—A machine-drill for quarries, mines, rock-excitation, etc.
- Rocker, Brush.**—In a dynamo-electric machine or electric motor, any device for shifting the position of the brushes on the commutator cylinder.
- Rock-faced**—**quarry-faced.**—The natural face of the stone, without dressing.
- Rocking-bar.**—A bar supporting a furnace-grate so that the grate can be tipped when desired.
- Rocking-pier.**—A bridge-pier hinged at the bottom, to accommodate the change in length of span, i. e., the expansion and contraction, due to temperature changes. Sometimes used in suspension bridges.
- Rock-oil.**—Petroleum.
- Rock-shaft**—**rocker-shaft**—**rocking-shaft.**—A shaft that rocks on its journals but does not revolve entirely.
- Rockwork**—**quarry-faced masonry**—**rock-faced masonry.**—See *Rock-faced*. Squared masonry with the face of stones left undressed.
- Roll-joint.**—A metal joint made by rolling one edge over the other and pressing the joint. Used in tinning roofs.
- Roof-plate**—**wall-plate.**—A plate on which the lower ends of the rafters of a roof rest.
- Rope-clamp.**—The metal attachment on the end of a rope or cable and forming a part of it.
- Ropewalk.**—A long shed in which rope is made.
- Rosin (and Resin).**—The residuum of distilled turpentine. (See page 481.)
- Rotary pump.**—A pump having rotary parts as fans to force the liquid ahead. A centrifugal pump is a rotary pump.
- Rubble.**—Rough stones used in rubble-masonry or rubble-work; irregular, for common rubble-masonry, and squared for ranged rubble-work.
- Rubble-Concrete masonry.**—See *Cyclopean Masonry*.
- Rundle.**—The rung or round of a ladder.
- Running-trap.**—A depressed U-shaped section of a pipe, to contain water at all times and guard against the escape of gases.
- Rustic.**—Various classes of facings for masonry including rockwork.

S.

Sack-hoist.—An endless-chain device for hoisting filled sacks, as grain, cement, etc.

Saddle.—Anything resembling a common saddle. A block resting on rollers on top of the pier of a suspension bridge to give the proper relief for expansion and contraction of cables; in such a case the resultant pressure is vertical. A chair for rails. The ridge-tile of a roof is often saddle-shaped and hence called saddle-tile.

Saddle-joint.—In tinning, etc., a joint made thus  between two metal plates.

Saddle-plate—crown-sheet.—In locomotive boilers, the bent plate forming the arch of the furnace.

Safety-cage.—A mining cage or elevator car provided with a parachute or a safety clutch in case of breakage and too rapid descent.

Safety-catch—safety-stop.—A catch to hold an elevator in case of breakage of cable.

Safety-lamp.—A lamp used in coal mining and safe when even the inflammable coal-gas is present, from igniting the latter.

Safety-valve.—A relief valve in a steam-boiler.

Sag.—A downward curved bend, or depression.

Salient.—Projecting outward. A salient angle is one pointing outward, as in a common polygon; opposed to reentrant.

Saltern.—A salt-works, or place where salt is obtained by boiling or evaporation.

Saltpeter—saltpetre.—Potassium nitrate, or nitrate of potash. Common name, *niter*.

Sand-bag.—A bag of sand or earth, used for repairing leaks or breaks in foundation work under water.

Sand-blast.—A stream of sand driven through a tube onto iron-work for the purpose of removing paint, scale, rust, etc., preparatory to repainting or welding. Used in portable form in welding rail-joints. The sand is forced by a sand-blower.

Sand-pump.—A sludger used to remove the pulverized rock in rope-drilling in the oil regions. A sand-ejector used in caisson-work for bridge foundations.

Sand-trap.—A device consisting of a kind of pocket or chamber for collecting sand and the heavy sediment from water in pipes, etc.

Saw-set—saw-wrest.—A tool for springing the teeth of a saw alternately to right and left in order that the kerf will be wide enough not to bind the blade.

Scabble.—To dress off the rough projections of a stone with a broad chisel or stone-axe or heavy pointed pick preparatory to finer dressing.

Scale.—A flake or crust on iron due to oxidation, when hammered or rolled (milled); hence hammer-scale, mill-scale, etc. A flux is used to prevent scale.

Scaling-hammer.—A hammer used to remove scale.

Scantling.—A small stick of timber not over say 5 x 5 ins. in section.

Scarf—scarf-joint.—A joint for splicing the ends of two timbers together so as to make a continuous stick; may be reinforced by iron straps and bolts, and also be keyed. A usual form is:

Scarp.—In fortifications, the inner slope of the ditch. A slope.

Scoring.—In founding: The cracking of a casting when unequal cooling takes place; frequently happens to pipes and cylinders when the core does not give way to the contraction of the surrounding metal.

Scotia.—A receding or concave molding, as at the base of a column.

Scouter.—In stone-working, one who removes large projections by boring slanting or transverse holes and using the necessary tools for splitting, as wedges, etc.

Screed.—One of several strips of plaster 6 or 8 ins. wide and a few feet apart dividing a surface to be plastered, into bays; the screeds are flushed out to the same plane and serve as guides in bringing the whole surface to that plane.

Screw.—One of the six mechanical powers or simple machines, namely, *lever, wedge, wheel and axle, pulley, screw, and inclined plane*.

Screw-bolt.—A bolt headed at one end and provided with a screw-thread and nut at the other end.

- Screw-gear.**—An endless screw working in the teeth of a pinion; a worm-screw working in a worm-wheel.
- Screw-pile.**—A pile with a screw at the lower end.
- Screw-pin.**—A cylindrical pin with a screw (and nut) at the end to hold it in position.
- Screw-wheel.**—A wheel which gears with an endless screw.
- Screw-wrench.**—A wrench having one or both jaws operated by a screw.
- Scribe.**—A pointed instrument for marking lines on wood, brick, metal, etc., as guides for cutting or scribing.
- Scroll.**—A convolved or spiral ornament resembling a partly unrolled sheet of paper or the letter S. The spiral ajutage around a reaction water-wheel.
- Scupper = scupper-hole.**—One of several openings in the side of a vessel at the deck level, for the escape of water.
- Scupper-nail.**—A short nail with a broad head, for nailing canvas, etc.
- Scuttler.**—A small hatchway in a vessel's deck; a hole in the side of a ship; a hole for sinking or scuttling a ship.
- Sea-breeze.**—A breeze from the sea toward the land.
- Season.**—To dry, as timber.
- Seat-earth = seat-stone = under-clay.**—In coal-mining, the bed of clay which characteristically underlies coal-seams.
- Sea-wall.**—A wall (generally artificial, but sometimes thrown up by the waves) to prevent encroachment of the sea.
- Second, Ampere.**—One ampere flowing for one second.
- Second, Watt.**—A unit of electrical work. A volt-coulomb.
- Secret.**—Covered up or hidden; thus, secret block, secret dovetail, secret nailing.
- Section-liner.**—An instrument for drawing parallel lines at certain distances apart, and consisting of triangle, straight-edge, scale and set-screw.
- Sector.**—A toothed gear comprising only an arc of a circle, for reciprocating motion; sector-gear. An astronomical instrument for measuring differences in declination. Sector of a circle is the area between two radii and the included arc.
- Segment.**—A distinct part of anything. Segment of a circle is the area included between arc and chord.
- Segment-gear.**—A gear extending over an arc only, for reciprocating motion.
- Segment-rock.**—A rock or cogged arc oscillating on a center.
- Seismograph = seismometer.**—An instrument for recording earthquake phenomena.
- Seize.**—To fasten together with small rope, cord or twine, by winding around it, as the end of a large rope, etc.
- Semi-columnar.**—Like a semi-column or half column appearing on the face of anything, as on a wall.
- Semi-dome.**—A half dome abutting a surface.
- Semi-fused.**—Half melted.
- Septangular.**—Having seven angles.
- Serrated.**—Notched or toothed, as a saw.
- Serve.**—To bind or wind around with twine, cord or marlin, as a rope, in order to protect it from rubbing and wearing.
- Service-pipe.**—A pipe for supplying water, or gas, etc., to a building, from a main.
- Set.**—The lateral bend of a saw-tooth. The last coat of plaster on a wall preparatory to papering.
- Set-screw.**—A screw for binding two or more things together, as in a cramp. A screw acting in a collar and with a point, for pressing into the metal of a shaft or other member to bind them together.
- Sextant.**—An instrument for measuring angular distances between objects. Used in navigation for obtaining latitude and longitude.
- Shackle.**—An unclosed link at the end of a chain, consisting of a U-shaped piece of iron fitted with a bolt (shackle-bolt) across the mouth, the shackle-bolt being held in place by a pin called a shackle-pin. A sort of clevis.
- Shaft.**—In mining and tunneling, a vertical hole, pit or well from the ground surface. The main body of a column. The interior of a blast-furnace above the hearth. In machinery, a large axle supporting something which revolves or oscillates.
- Shank.**—The long part of anything as the stem of a key or of an anchor, the shaft of a column, the holding part of a drill, the body of a bolt, etc.

- Shear.**—The transverse stress in a girder at any cross-section, tending to make that part of the girder on the left (or right) of the section slide along the plane of the cross-section. A shear in any direction has an accompanying and equal shear at right angle to it; thus we have longitudinal shear in a beam. Rivets may be in single shear or double shear, the latter when connecting three bars the middle one of which is pulling in a direction opposite to that of the two outside bars.
- Shears** (formerly sheers).—Two or more poles fastened together near their tops, with their lower ends or legs spread apart as a base, and supporting hoisting tackle. Called *shear-legs*.
- Shear-steel.**—Blister-steel especially prepared and suitable for making shears, knives, etc. When re-worked, it is called *double shear steel*.
- Sheathing.**—A thin covering, as with plates, boards, etc.
- Sheave.**—A grooved wheel, as the wheel of a pulley.
- Sheeting** = **sheet-piling** = **sheet-timbering.**—Timber or metal piles, sheets or boarding driven to form a more or less water-tight lining, and used in connection with the construction of foundations under water, tunnel lining, etc.
- Shellac.**—A resinous substance possessing valuable insulating properties, which is exuded from the roots and branches of certain tropical plants.
- Shim.**—A sort of flat wedge to separate the surfaces of two adjacent bodies by wedging them or holding them apart. Wooden or iron shims are used in spacing rail-joints in track-laying. Heavy machinery is often shimmed up from the floor.
- Shingle.**—Stones on the sea-shore, a little coarser than gravel.
- Ship-worm** = **teredo** (*T. navalis*).—A worm that bores into and honeycombs timber and piling under water.
- Shoe.**—A metallic piece usually shaped to fit the end of various things, as the shoe or metallic point of a pile, or the malleable or cast fitting at the connecting ends of the bands or wood-stave pipe, etc.
- Shore.**—A prop or temporary support for bracing up anything, as a ship, or the sheeting in a sewer-trench, etc.
- Shot.**—A blast.
- Shroud.**—One of the ropes from the side of a ship to the mast-head, to support the mast.
- Shunt.**—To establish an additional path for the passage of an electrical current or discharge.
- Shuttle.**—A gate to allow water to flow on a water-wheel. A section of a shuttle-dam.
- Side-beam.**—One of the two beams of a side-beam engine.
- Side-hatchet.**—A hatchet with only one side of the blade chamfered.
- Siding.**—A short piece of railroad-track lying along the main track and used for passing of trains, etc. The boarding of, or for, the side of a building.
- Silt.**—An earthy sediment, or deposit of fine soft mud from standing water or a running stream.
- Sink.**—To excavate downward, as a shaft.
- Sinusoid.**—A curve of sines, the angles being laid off as abscissas, and the sines as ordinates.
- Siphon.**—A bent tube like an inverted V but with unequal legs, the shorter leg inserted in the basin of water. When the tube is thus placed and is filled with water, the water in the basin will be discharged through the tube unless air collects in the latter and stops the siphonic action.
- Siphon, Electric.**—A siphon in which the stoppage of flow, due to the gradual accumulation of air, is prevented by electrical means.
- Sister-hooks** = **clip-hooks** = **clove-hooks.**—A pair of hooks which close together like the jams of tongs and fit together side by side.
- Size.**—A gelatin wash used by painters.
- S-joint.**—A metal joint, thus 
- Skew.**—Opposed to right-angled. Oblique. We have skew gearing, skew bridges, skew abutments, skew arches, etc.
- Skewback.**—The inclined stone or surface which takes the thrust of the arch.
- Skid.**—Any simple arrangement of one or more (generally two) poles or timbers placed on an incline (usually), for sliding or rolling freight upon in unloading from a car or vessel, etc.
- Skirting-board** = **baseboard** = **mop-board** = **wash-board.**—A narrow board placed around the walls of a room next the floor.

Sledge.—A large heavy hammer; a sledge-hammer.

Sleeper.—A piece of wood or metal laid on the ground to support various classes of construction as rails of a track, floors of houses, etc. A tie.

Sleeve.—A hollow pipe, tube, or thimble, slid over the ends of two cylinders to be joined together.

Slide-bar.—A bar which is slid over the draft-opening of a furnace. One of the guides for the cross-heads of a piston-rod.

Slide-box.—The slide-valve chest of a steam engine.

Slide-rod.—The rod which operates the slide-valve of a steam-engine.

Slide-valve.—A valve which slides two and from its seat.

Slip.—A sledge, or skip without wheels; used in coal-mining.

Sling.—A short rope or chain placed around anything to be hoisted.

Slip.—A docking place for vessels.

Slope-wall.—A wall built along a stream to prevent the bank from wash.

Sludge.—In mining, the finely powdered stone, mixed with water, in a drill-hole. Refuse from coal-washing and other operations in mining, and in the refining of crude petroleum. The deposited sediment in sewage tanks after the sewage is treated with chemicals.

Slug.—In mining, a loop in a rope through which a man puts his leg when being raised or lowered in a shaft.

Sluice.—A wooden trough which miners use in washing gold from gravel and sand. An artificial channel. A body of water held in check or flowing through a flood-gate or sluice-gate. The injection-valve to a condenser.

Sluice-gate = flood-gate.—The gate of a sluice.

Smoke-box.—A chamber through which smoke and gases pass from the furnace to the chimney.

Snap.—A tool used in riveting, to form the new head.

Snap-hook.—A metal hook with a spring-mousing to prevent the object hooked from slipping off.

Snatch-block.—A pulley-block with an opening on the side so that the bite of a rope can be passed over the sheave; when in use, the opening is covered by a strap.

Snip.—To cut off. In carpentry, to cut off nearly or quite at right-angle with the length of the timber. But see Snipe.

Snipe.—To cut off on a long bevel. In carpentry, to make long beveled cuts at the end of a timber, in framing the end to smaller section than the main timber.

Snub.—To check quite suddenly, as the speed of a boat; the checking is done by a snubbing-line, passed around a post called a snubbing-post.

Soaking-pit.—A pit in which cast ingots are placed so the mass may cool to a uniform temperature suitable for rolling.

Socket-bolt.—A bolt that passes through a thimble placed between the parts connected by the bolt.

Socket-chisel.—A form of heavy chisel for mortising.

Socket-drill.—A drill for enlarging or countersinking drilled holes.

Socket-joint.—An articulated-, flexible-, or ball-and-socket joint, as a flexible joint in a pipe-line. Flexible-joint pipes are used as water- and gas mains across streams; they are jointed together on a scow and sunk in a continuous line as fast as connected, the last joint being always out of water.

Soffit.—The lower surface of an arch; extended also to include the lower surface of a span over a door or window opening.

Solder.—A fusible alloy for uniting metal surfaces or joints. There are a great variety of solders for different metals. Hard solders, composed of copper and zinc, and called *spelter*, are used for uniting iron, copper and brass. Soft solders, composed of lead and tin, are used for uniting tin or lead.

Sole.—Anything resembling in function the sole of a shoe. The foundation-plate of a marine-engine. The lower edge of a turbine.

Solenoid.—A cylindrical coil of wire the convolutions of which are circular.

Sounding.—To measure the depth of water, soft mud, etc. In shallow water this may be done with a graduated rod or pole. In deep water, various kinds of apparatus are used; some of them, in addition to measuring the depth of water, are provided with a device for bringing to the surface samples of mud from the bottom of the sea.

Spall.—A piece chipped from a stone, as with a spalling-hammer.

Spandrel.—The triangular-like portion or space of an arch lying above or outside the extrados, and below the roadway.

- Spandrel-filling.**—The filling of earth, or masonry, etc., in the spandrel of an arch.
- Spandrel-wall.**—A wall built on the extrados of an arch in the spandrel; used to give rigidity to the arch, or to support the roadway, etc.
- Spanner.**—A sort of lever-wrench with a hole or with movable jaws to fit over a nut for tightening it; or any instrument for claspings and tightening a nut or screw or wheel, etc. A rod connecting two parts having parallel motion.
- Spar.**—A round stick of timber used for various purposes, as the jib or boom of a derrick, the masts, booms and yards of a ship, the poles or common rafters of a roof, etc.
- Spark-arrester.**—A netting or device placed over or in the smoke-stack to prevent the escape of the sparks.
- Spectroscope.**—An instrument for producing a spectrum from rays of light, and for studying it.
- Spectrum.**—The continuous and successive colors in a band of light seen when rays of light are deflected through a prism.
- Speculum-metal.**—An alloy consisting of ten parts copper and one part tin; used as a mirror or speculum.
- Speed-pulley.**—A sort of cone-pulley, but stepped; different speeds are obtained by placing the belt over different steps or faces of the pulley.
- Spelter.**—Zinc. Spelter solder is hard solder composed of copper and zinc.
- Spider, Armature.**—A light framework or skeleton consisting of a central sleeve or hub keyed to the armature shaft, and provided with a number of radial spokes or arms for fixing or holding the armature core to the dynamo-electric machine.
- Spiegeleisen = spiegel-iron.**—A pig-iron containing from $\frac{1}{2}$ to $\frac{1}{6}$ or more of manganese; used in the manufacture of Bessemer steel.
- Spigot.**—A plug with a hole in it and used as a faucet. The end of a cast-iron pipe which fits into the bell-end of an adjoining pipe; such a joint is called a *spigot-joint*.
- Spike.**—A large metal nail; may be pointed, chisel-pointed, barbed, grooved, or split, etc.; the head also may be variously shaped.
- Spile.**—A pile.
- Spillway.**—A sort of weir or gap or passage for surplus water from a reservoir; located near one end of the dam or at the dam itself.
- Spindle.**—A thin axle or shaft. A solid generated by a curve about its chord; may be circular, parabolic, elliptical, etc., depending upon the curve.
- Splay.**—The flaring or widening at the mouth of anything. The wings of a culvert when they spread back from the center line are said to be splayed.
- Splice.**—The joining of two pieces together by overlapping.
- Spoil-bank = waste-bank.**—A refuse bank in mining and in general excavation.
- Springer.**—The lowest voussoir or arch-stone of an arch.
- Springing-line.**—The lower face-line of the springers of an arch; the line from which the arch springs or rises or begins.
- Spring-pole drilling.**—In rock-boring, a simple method of using a spring-pole on the outer end of which is suspended the drill-rod. The spring of the pole raises the rod, the down motion being effected by hand.
- Sprocket-wheel.**—A *rag-wheel* or wheel with projections that engage the links of a chain passing over it. The projections may be pins, teeth or lugs, etc.
- Spur-gear = spur-gearing.**—Gearing in which spur-wheels are used.
- Spur-wheel.**—A common cog-wheel, the cogs being on the periphery of the wheel, and radial.
- Square.**—An instrument for laying off right angles. In roofing and flooring, an area equal to ten feet square = 100 sq. ft.
- Square-headed.**—Straight, as the upper edge of the opening of a door or window not arched or curved.
- Stack.**—One or more main flues, funnels, or chimneys grouped together for the passage of smoke. A smoke-stack.
- Staff-angle.**—In plastering, a square rod of wood flush with the wall at the external angle of a room, to protect the plastering.
- Staging.**—A temporary structure, including the flooring and supports, used in building operations.
- Stamp-mill = stamping-mill.**—A mill for crushing ore by the use of vertically-acting stamps; may be operated by any kind of power.

- Stanchion.**—A vertical support, as a column, post or strut used as a support to a vessel's deck, or part of a roof, etc.
- Standing.**—Anything quite permanent, as standing-rigging or the shrouds and stays of a ship. Anything rigidly fastened to and projecting from, as a standing-bolt, or stud-bolt.
- Stand-pipe.**—A vertical water-pipe used as a reservoir; or inserted in a main to show the hydraulic grade line or to act as an air-valve; and for other purposes as in a steam-engine.
- Staple.**—A U-shaped loop of metal driven into a door or other object, the projecting ends being bent or clinched on the inside, to receive a hook or hasp and form a kind of lock.
- Starboard.**—The right side of a vessel facing her bow. Opposed to *larboard* or *port*.
- Starling.**—A pile structure around, or up-stream or down-stream from, a bridge-pier for protection or support. One of such piles.
- Static—statical.**—Pertaining to weight, without motion; as static equilibrium, static load, static pressure, etc.
- Stay.**—A rope, tie, brace, or strut, etc., for keeping anything in place or making it "stay" in position.
- Stay-bolt.**—A bolt used to prevent two opposite plates or parts from being pressed or pulled apart further, as a stay-bolt in a steam-boiler.
- Stay-rod.**—Same as stay-bolt but longer, and used for various purposes as in building-construction.
- Steam-box—steam-chest.**—A reservoir or chamber for steam to be used; situated above the boiler, in a locomotive. From this chamber the steam passes to the cylinders.
- Steam-chest.**—[The common name.] Same as *Steam-box*, above.
- Steam-pipe.**—A pipe which leads from the boiler to the engine or from the boiler to the steam-chest. Various pipes conveying steam.
- Stem.**—A projecting part, as the stem of a gate-valve.
- Step.**—In mechanics, anything resembling a step of a stair, as an offset on a cone-pulley. The foot or bearing of a vertical shaft.
- Stile.**—One of the main frames of a door to which the secondary or central frames are secured. The outer frame or main frame of anything.
- Stilted-arch.**—In architecture, an arch apparently raised above its springing as if stilted.
- Stirrup.**—In carpentry, an iron loop or strap for supporting one beam butting another, or a rafter, etc.
- Stock and die.**—A die and its holder, for cutting screws.
- Stoker.**—A fireman. A *mechanical stoker* is an automatic device for feeding fuel in a furnace and attending to the ashes, etc.
- Stone-breaker.**—See *Rock-crusher*.
- Stone-saw.**—A blade made to reciprocate in its kerf while sand is fed by a stream of water. Used for sawing marble, etc.
- Stope.**—An (horizontal) excavation in a mine, from a shaft or tunnel or drift, to remove the ore laid bare, or to pile the ore, or to receive refuse, etc.
- S-trap.**—An S-bend in a waste pipe to prevent gases from rising above the point of bend.
- Strap.**—A long narrow strap-like piece of metal, either straight or looped, and bolted to two pieces to hold them together, as in an iron strap used in a timber splice, etc.
- Stratified.**—Deposited in layers or strata. One of the layers is called a stratum. In geology, stratified rock or earth; bed rock.
- Stress.**—A force producing strain; measured in lbs. per sq. in. or per sq. ft. on the member to which it is applied. Within the elastic limit of the material, *stress is proportional to strain*—Hook's Law.
- Stress-sheet—strain-sheet.**—A diagram of a structure, as a bridge, giving stresses and sizes of members and other information which will determine the character of the structure to be built.
- Stretcher.**—In masonry, a brick or stone laid horizontally in the direction of the face of the wall; distinguished from header which heads onto the face of the wall.
- Stretcher-bond.**—Bricks or stones all laid as stretchers in continuous courses, no two joints being opposite transversely.
- Stria.**—A fillet between the flutes (base moldings) of columns.
- Strike.**—The direction, by the compass, of a stratified formation; at right angle to the *dip*.
- Striking-plate.**—In arch-centers, one of a series of compound wedges on which the centering rests while the masonry arch is being built; and

when the wedges are struck, the centering lowers and the arch becomes self-supporting.

String.—A string-course. A line of pieces used in construction, as timber, stone, etc.

String-course.—In architecture, a projecting molding or other prominent or distinct band.

Stringer.—A *string-board* or *string-piece* of a stair, or one of the slanting pieces supporting the treads and risers; or an ornamental piece fitted outside the supporting stringer. A longitudinal piece for supporting anything such as the ties or planking on a bridge.

Stripping.—In a quarry, mine or gravel-pit, the useless material stripped or removed preparatory to opening the quarry, mine or pit.

Strut.—A member acting in compression. Opposed to *tie* which acts in tension. A prop or brace.

Stub.—A short end or blunt end.

Stub-end.—The enlarged end of a connecting-rod or pitman, to which the strap is fastened.

Stud.—One of the vertical pieces of scantling in a partition and to which the laths are nailed.

Stud-bolt.—See *Standing-bolt*.

Studding.—In carpentry, material to be used as studs or joists.

Stuffing-box.—A sort of cast-iron box or chamber arranged around a movable rod to secure a tight joint against water, steam, or air, etc., passing along the rod through the wall which the rod pierces. The box is packed with greased hemp, or india-rubber, etc., and the ring-cap screwed or bolted on.

Suction.—The removal or the lessening of the atmospheric pressure on any part of a liquid so as to disturb its equilibrium and cause it to flow, the atmospheric pressure still remaining on some other surface of the liquid. The exhaustion of a gas or liquid from a chamber.

Suction-pipe.—A pipe connected with the bottom of a pump-barrel and leading down into a well or body of water to be raised. A pipe leading from beneath a water-wheel downward to the level of the tail-race in order to make the total head or fall available for power; the pipe must be air-tight.

Suction-pump.—A pump with a barrel or cylinder standing on and fastened to a suction-pipe leading to a well; at the junction of barrel and pipe is a flap-valve raising upward to allow water to enter from below, but which closes down tight against any back pressure; the barrel itself being fitted with a piston-rod operating a piston-head containing a flap-valve which also raises in the same manner as the other valve. At the down-stroke of the piston the lower valve closes and the upper one opens; at the up-stroke they reverse. Other kinds of valves may be used.

Suction-valve.—The lower valve of a suction-pump; the one below the piston. See *Suction-pump*.

Sump.—A depression in which water collects, as at the head of a landslide; a kind of pool. A reservoir in a mine or other working into which drainage water is led and from which it is pumped out of the working; a *sump-pump* is used for this purpose, and the shaft through which it is pumped is called a *sump-shaft*.

Surbase.—An upper molding above a base, as that above the wainscoting or at the top of a pedestal.

Surd.—In mathematics, a quantity which cannot be expressed definitely, as $\sqrt{3}$.

Surface-condenser.—A condenser in which the exhaust-steam is condensed on metal surfaces which are cooled by flowing cold water in contact with the opposite faces.

Surface-tension.—The adhesion or tension of the surface-skin of a liquid, as when anything is made to touch it and is then raised. A kind of capillary attraction.

Swage.—A sort of die for giving shape to a piece of metal being hammered.

Swage-block.—A block with various holes, grooves, and other shapes for swaging or shaping pieces of metal, as for heading bolts, etc.

Sway-brace.—A brace used to cut a four-sided panel of a structure into rigid triangles. A sort of diagonal member or brace (strut or rod) between two opposite posts of bridge trusses.

Swing-saw.—A circular saw suspended from a frame and which can be used in sawing large bulky pieces at rest.

- Switch.**—Any device for connecting or disconnecting, as a track, a current of electricity, etc.
- Switchback.**—A sort of zig-zag location of a railway, for gaining a gradual grade over a mountain.
- Swivel.**—A fastening comprising an axis which may be turned around freely in the other part, the end of the axis being headed like a bolt, to sustain tension.
- Synchronize.**—To cause to occur or act simultaneously.
- Synclinal.**—In geology, the dipping of strata toward each other and forming valley shapes. Opposed to *anticlinal*. A *synclinal axis* is a line following along the lowest points of the depression.
- System, Three-Wire.**—A system of electric distribution for lamps or other translating devices connected in multiple, in which three wires are used instead of two usually employed. In such a system two dynamos are usually employed, connected in series.

T.

- T = tee.**—Anything resembling the letter T, as a T-rail, T-square, T-iron, etc.
- Table.**—In mechanics, the table-like part of a machine on which the work is placed. In architecture, a horizontal molding or a projecting portion from a wall.
- Tackle.**—A rope operating in one or more pulleys for hoisting or hauling.
- Tail-race.**—A channel and stream of water leading from the water-wheel.
- Talus = batter.**—Slope, as of a parapet or rampart, in fortifications.
- Tamp.**—To force down with strokes or pressures, as tamping a charge of powder in a hole, or tamping earth, concrete, etc.
- Tamping-bar = tamping-iron.**—In blasting, an iron bar for forcing the tamping (material) on the charge of explosive in the hole.
- Tamping-plug.**—A form of cast-plug used instead of tamping material in a blast-hole.
- Tangent-screw.**—A sort of slow-motion screw for revolving circular disks slowly.
- Tank-engine.**—A locomotive that carries its coal and water without a tender.
- Tank-iron.**—Plate iron whose thickness is between that of boiler-plate and sheet-iron, the latter being the thinnest and about the same as stove-pipe iron.
- Tap.**—A tool with an external, tapered, and longitudinally-grooved screw for cutting the internal screws of nuts, etc. As a verb, to make a tap as in a pipe (pipe-tap); to bore or cut into; to pound as with a hammer in testing rivets or cast-iron pipe.
- Tap-bolt = tap-screw.**—A bolt screwed into a tapped hole, as in a plate, the plate acting as a nut.
- Tapping-drill = tapping-machine.**—A drill or machine for tapping holes in street-mains, or iron pipes.
- Tappet.**—A projection or arm on a revolving shaft, which strikes or taps something at each revolution.
- Tee = T.**—See T.
- Teeth.**—Plural of tooth; see *Tooth*.
- Telford pavement = telford.**—A road pavement consisting of a foundation of small stones laid by hand; on top of and in the crevices of these stones are packed smaller pieces; upon this, is broken stone. The whole mass is rolled until the surface becomes compact and smooth.
- Temper.**—To modify. To bring metal to a proper degree of hardness by first heating to a high temperature, and then suddenly cooling in a bath of oil, or water, etc. To mix mortar to the right consistency for bricklaying, etc.
- Templet = template.**—An outline of anything, used as a guide or model in shaping it, as the edge of a board cut to shape a molding, or a board or plate with holes spaced for punching other plates, etc.
- Tender.**—That which tenders or waits upon, as an engine tender, or a vessel supplying freight, provisions, etc., to another.
- Tenon.**—The framed projection at the end of a timber, to fit into a mortise; such a joint is called a *mortise and tenon* joint.
- Teredo = ship-worm.**—A sea-worm which bores into and honeycombs piling and timber.
- Terne-plate.**—An inferior tin-plate, or a plate of sheet-iron or sheet-steel coated with tin which is largely alloyed with lead.

- Terrace.**—A sort of long horizontal step in an embankment; used on the sloping up-stream and down-stream faces or slopes of earthen dams. A kind of bench or level, on the side of a hill.
- Terra-cotta.**—A fine quality of clay baked very hard; used for brick, roofing tile, pipes, etc.
- Test-pump.**—A force-pump used for testing the strength or tightness of pipes, cylinders, etc. It is provided with a pressure-gage.
- Theodolite.**—A surveying instrument, something like a transit but whose telescope is not reversible.
- Thermometer.**—An instrument for measuring temperatures. *Centigrade thermometer* reads zero at freezing and $+100^{\circ}$ at boiling. *Deep-sea thermometer* used to record the temperature of the water at any depth in the sea. *Differential thermometer* is used to record small differences in temperature. *Fahrenheit thermometer* reads $+32^{\circ}$ at freezing and $+212^{\circ}$ at boiling. *Maximum thermometer* registers the maximum temperature. *Minimum thermometer* registers the minimum temperature. *Reaumur thermometer* reads zero at freezing and $+80^{\circ}$ at boiling.
- Thimble.**—A sleeve or tube used to join the ends of pipes or rods. A circular ring, concave outside, to form the inside protection to a loop of rope when suspended on a hook or other contrivance.
- Thimble-joint.**—A sleeve or thimble slipped over a pipe-joint and packed to prevent leakage during expansion and contraction.
- Thread.**—The spiral ridge or worm of a screw.
- Three-ply.**—Three thicknesses, as three-ply roofing felt.
- Throat.**—The narrow part of an opening, not always near the end, as the throat of a venturi-meter.
- Through-mortise.**—A mortise cut entirely through a timber.
- Through-stone—thorough-stone.**—A header extending entirely through a wall.
- Throw.**—The distance moved, as the throw of a railroad switch is from 5 to 6 inches. The extreme movement of a slide-valve. The double-radius of a crank.
- Thrust.**—The crushing of the pillars in a coal-mine.
- Thrust-box.**—A box-bearing sustaining a vertical shaft.
- Tide-gate.**—A gate through which water passes into a basin when the tide flows in, and which is shut to retain the water from flowing back at ebb.
- Tie.**—Any beam or rod used in construction to hold certain parts together by tension or pull. One of the sleepers or supports to the rails.
- Tie-plate.**—A metal plate resting on a tie and supporting the rail; used to prevent the flange of the rail from sinking into the wooden tie.
- Tie-rod.**—Any rod used as a tie to sustain tension or pull.
- Tile.**—A thin shape of baked clay, used for covering roofs, floors, walls, etc.; also for pipe, drains and sewers.
- Tire.**—An outside ring around the periphery of the wheel of a vehicle. In common wagons, the metal tire is heated so as to expand and then shrunk over the wooden felloe.
- Tit.**—A small projection, as like the end of a bolt on the surface of a casting.
- Toe.**—The sharp end, or front end, or moving end of many devices. The toe of a switch, or of a frog, etc.

Toggle-joint.—A joint formed by two bars hinged together at an obtuse angle so that when direct pressure or pull is applied at the joint the lateral force is greatly augmented.

- Tongue.**—Many things pointed or projecting, as the bead or tongue along one edge of a board to fit into the groove of an adjacent board; called *tongue and groove*, and used for flooring, etc. The pointed part of a crossing-frog.
- Tooling.**—In masonry, dressing with a chisel so the face shows the parallel marks of the tool with uniformity.
- Tooth.**—One of the teeth or cogs of a wheel. Also applies to other tooth-like projections as in a saw.
- Torus.**—A large convex molding, used at the base of a column. Opposed to *scotia*, a concave molding.
- Tower, Electric.**—A high tower provided for the support of a number of electric arc lamps, employed in systems of general illumination.
- Tower, Electric-Transmission.**—A tower on a transmission line, for supporting long-span wires.

- Traction-wheel.**—A wheel which by friction on its circumference draws a vehicle, as the driver of a locomotive.
- Traction-engine.**—A steam-engine for drawing loads on common roads.
- Trailing-wheel.**—One of the wheels situated just behind the driving-wheels of a locomotive to support the rear weight.
- Train.**—A set of wheels, as cog-wheels, working in series, i. e., connected together in a train.
- Trammel.**—An instrument for drawing an ellipse; consists of a horizontal arm with a vertical pencil at one end, two points of the arm working along lines which cross each other at right angle.
- Transformer.**—An induction coil used for *raising* or *lowering* the electromotive force at any point of a circuit. The E. M. F. is raised by the step-up transformer, and lowered by the step-down transformer. Other terms are: Commuting-, Constant-current-, Core-, Hedgehog-, Lightning-arrester-, Multiple-, Oil-, Open-iron-circuit-, Pilot-, Rotary-current-, Rotary-phase-, Series-, etc.
- Transom.**—One of the horizontal framing timbers across the stern of a ship. A horizontal beam across the opening for a door. The opening above a door. A horizontal beam of timber or stone across a window.
- Trap.**—A pipe with a depressed bend to hold water and thus form a water-seal against the passage of gases; usually U- or S-shaped; used in closets in connection with soil-pipes, and elsewhere.
- Trap-valve**—**clack-valve.**—See *Clack-valve*.
- Traverse.**—In surveying, a polygonal base-line around a piece of land to be surveyed, showing distances and angles.
- Tread.**—The horizontal part of a step, the vertical part being the *riser*.
- Treadle.**—A foot-lever, for operating a sewing machine, grindstone, or lathe, etc.
- Greenail.**—A long wooden pin (hard wood) for fastening planks and timbers; used in ship-building. Auger-holes are first bored, and the pins driven in.
- Trestlework.**—A stilted framework for supporting the floor of a bridge or other structure.
- Trimmer.**—In carpentry, a short cross-joint inserted at right angle between two lines of joists and butting against them; and in turn supporting the ends of other joists parallel with the main ones. The ends may be supported by iron stirrups, or mortised into the other joists. Used at floor- and roof-openings, at chimneys and stairways.
- Trip-gear.**—A gear that trips the valve-closing mechanism in a steam-engine when the piston reaches a certain definite position.
- Trip-hammer**—**tilt-hammer**—**tilting-hammer.**—A hammer operated by a cam which trips a lever and allows the hammer to fall; used for heavy work.
- Tripod.**—A three-legged support, as for surveying-instruments, screw-jacks, drills, etc.
- Tripper.**—A part of a machine which causes another part to be released, as the tripper of a pile-driver hammer.
- Trippet.**—Any projecting part of a machine that trips.
- Truck.**—A framework with two or more pairs of wheels for supporting one end of a car or locomotive. A bogie-truck is used forward of the drivers and is carried by the bogie-wheels; this name also applies to street-car trucks. Also, a wagon with a solid platform for hauling heavy material.
- Trundle-wheel**—**lantern-pinion**—**lantern-wheel**—**wallower.**—See *Lantern-wheel*.
- Trunk.**—A long trough or box for conveying water, as from a race to a water-wheel; a penstock or flume.
- Trunnion.**—One of the cylindrical projections on the side of a cannon, which support it in its carriage and on which it revolves in a vertical plane. A hollow gudgeon on either side of an oscillating cylinder, for supporting the cylinder and through which steam enters and is exhausted.
- Trunnion-valve.**—A valve of an oscillating-cylinder, and operated by its oscillating motion.
- Truss.**—A framework acting as a beam or girder.
- Truss-beam.**—A simple or compound (wooden) beam reinforced by one or more tie-rods (or in some cases, A-shaped struts).
- Tube, Crookes'.**—A tube containing a high vacuum and adapted for showing any of the phenomena of the ultra-gaseous state of matter.
- Tube-valve.**—A tube pressed against a seat at outlet, the other end projecting above the surface of the water; operated in various ways.

- Tudor style.**—A style of English architecture of the 16th century.
- Tumbler.**—A kind of lever which drops into a notch at a certain definite position in the movement of a mechanism, and locks.
- Tumbler-tank.**—A tank which automatically discharges its contents when filled; if two tanks, they alternate in filling and emptying.
- Tumbling-bay—waste-weir.**—That part of the outlet or waste from a canal or other body of water at which the water falls rapidly.
- Tumbling-box.**—A box pivoted at opposite ends or corners and made to revolve. A cubical concrete-mixer is a tumbling-box.
- Tumbling-shaft.**—A shaft used in stamping mills, in the link-motion of a locomotive, in thrashing-machines, etc.; a sort of a cam-shaft.
- Turbine.**—In the broadest sense: A motor with vanes (usually curved) and acted upon by the pressure or velocity (or both) of fluids, as air, gas, water, etc. (as ventilating fans, turbine water wheels, etc.); or acting upon fluids (as in the case of the centrifugal pump). In a restricted sense: A motor with curved vanes acted upon by fluids (water or steam), as the hydraulic turbine and steam turbine (see below).
- Turbine, Hydraulic—Turbine Water Wheel—Turbine.**—A turbine deriving its motive power from the pressure and velocity of water. See page 1342.
- Turbine, Steam.**—A turbine deriving its motive power from the velocity and expansive force of steam.
- Turn, Ampere.**—A single turn or winding in a coil of wire through which one ampere passes.
- Turnbuckle.**—A double-nut with right and left threads, used for connecting the ends of two rods or bars, making one adjustable member.
- Turning-point.**—In leveling, a temporary bench-mark.
- Turn-table—turntable.**—A sort of deck-drawbridge swinging in a horizontal circle, for turning locomotives; used at terminal points and at shops, round-houses, etc. There is a central pin or pivot-pin supporting the table, and the outer ends are steadied by wheels on a circular track.
- Turpentine.**—An oleoresinous substance obtained from the bark and wood of coniferous trees. The oil of turpentine is obtained by distillation.
- Tuscan Order.**—In architecture, one of the five Orders; similar to the Roman Doric.
- Tusk-tenon.**—A tenon stepped or shouldered into a mortise, to give additional strength to the connected beams.
- Two-ply.**—Having two thicknesses, or double thickness.
- Twyer.**—One of the tubes through which air enters a blast-furnace.

U.

- U-bolt.**—A U-shaped rod with nut and thread at each end.
- Unctuous.**—Oily; greasy, soapy. Having the nature of an unguent.
- Underdrain.**—A sub-drain, or drain under ground.
- Undermine.**—To render unstable by weakening the foundation. To excavate beneath, as by digging or washing.
- Underpinning.**—A support or new foundation placed under a wall not properly supported; it may be either temporary or permanent, and may consist in merely projecting the wall downward. The act of introducing such a support. The term *undersetting* may be used, especially with reference to machinery, pedestals, etc.
- Undershot wheel.**—A water-wheel operated by the force of the stream acting upon the blades or paddles as they fall below the level of the center or axis of the wheel.
- Undertow.**—A sub-surface current moving in a direction different from the surface-current.
- Unguent.**—Any soft substance or composition used for lubrication.
- Unicinal—monoclinal.**—In geology, dipping in one direction: a monoclinical fold is half an anticlinal fold.
- Unit.**—A standard of quantity in any system, as unit of measure, capacity, weight, force, etc.
- Upset.**—The end of a rod, or bar, etc., which has been thickened by shortening its length, for the purpose of connecting it with some other member so that the joint will not be weaker than the body of the rod or bar; as for forming the head of an eye-bar, or the upset-end on a rod for cutting a screw-thread. The machine for making upsets, or upsetting, is called an *upsetting-machine*. The shaping of eye-bar heads is called *forging*; welding a separate head on the body of the bar is not allowable in a good class of structural work.

V.

Vacuum-brake.—A device for stopping a train by the operation of brakes through partial vacuum created in a pipe connected with the locomotive; the vacuum being created by a steam-jet escaping through an ejector, and the brakes being operated by the drawing of the brake-rods which are joined to collapsing bellows connected with the pipes.

Vacuum-gage.—A gage for indicating the pressure (or the amount of vacuum) in any chamber, as in the receiver of an air-pump, a steam-condenser, etc.

Vacuum-valve.—A safety-valve opening inward in a steam-boiler to give relief from collapse when the partial vacuum in the boiler reduces the internal pressure below the point of safety in resisting the external atmospheric pressure.

Valve.—Any device for controlling the flow of liquid, vapor or gas through a pipe or passage. *Valve-chest*, in a steam-engine, is the steam-chest; it is the chamber in which the valve works. *Valve face*, that part of the surface of the valve which comes in contact with the valve seat. *Valve gear* = valve motion, the system which gives motion to a valve, as the link motion of a locomotive for regulating the supply and exhaust of steam to and from the cylinder. *Valve seat*, the fixed surface or piece on which a valve presses and rests. *Valve stem*, a rod attached to a valve to operate it. *Valve yoke*, a strap to hold a valve.

Air valve; a valve to regulate flow of air, as in a steam-boiler.

Automatic valve; a valve that works automatically, as a clack-valve.

Back-pressure valve; a valve to prevent back-flow when the direction or pressure of fluid is reversed.

Balance-valve; a valve admitting fluid to both sides under nearly equal pressure.

Ball-cock valve; a sort of ball float valve, as used in water-closet tanks.

Ball valve; a valve formed by a ball resting upon a seat.

Blow-through valve; a valve situated in the opening through which steam enters a condensing steam-engine, for blowing through.

Brake-shoe valve; in an air- or vacuum-brake, a valve to relieve the excessive pressure upon the wheel.

Butterfly valve; a double clack-valve, used in pumps.

Check-valve; a valve placed in a pipe-line, or boiler, to prevent back-flow.

Clack valve; a trap-flap, or clapper, hinged to allow flow in one direction only.

Cone-valve; a valve with a conical face and seat.

Conical valve; a T-valve or puppet valve—a circular metal plate with beveled edge and seat.

Cup-valve; a valve cup-shaped, and becoming a balance-valve if consisting of two cups connected by a stem through the opening.

Double-beat valve; a double-seat valve.

D-valve; a valve resembling the letter D, used in the induction and eduction passages of a steam-engine cylinder.

Equilibrium valve; a balance valve (see above).

Flap-valve; a clack-valve (see above).

Globe-valve; a valve with a globular casing.

Hinged valve; a butterfly-valve or clack-valve (see above).

Key-valve; an air valve-plug.

Lifting valve; a ball-, cone-, poppet-, or safety-valve.

Long-slide valve; a long-valve, governing parts of both ends of a steam-engine cylinder, especially of the Cornish type of engine.

Long-valve; a long-slide valve (see above).

Low-water valve; a valve which allows the steam to escape when the water in the boiler is too low.

Oscillating valve; a valve that oscillates.

Piston-valve; a reciprocating valve, alternately opening and closing the port of a steam-engine cylinder.

Pocketed valve; a valve fitted into the depression of a pocket.

Poppet-valve; a valve which lifts bodily from the seat.

Pat-lid valve; a cap valve used at the end of a pipe, or the cover of an air-pump of a steam-engine.

Puppet-valve; a conical valve or poppet valve (see above).

Regulator-valve; a throttle valve.

Relief-valve; a valve through which fluids escape at a certain determined high pressure.

- Reverse valve** or **reversing valve**; the valve of a reversing cylinder, often a plain slide-valve.
- Rotary valve**; a rock valve which acts by partial rotation.
- Safety-valve**; a valve to relieve excessive pressure, as in a steam-boiler.
- Screw-valve**; a screw with a point forming a small valve, for regulating flow.
- Slide-valve**; a valve which slides over a seat.
- Snifting-valve**; the tail valve or blow valve in the cylinder of a steam-engine, for the escape or admission of air.
- Spherical valve**; a ball valve.
- Throttle-valve**; a valve in the steam pipe of a boiler for controlling the flow of steam, as to a cylinder.
- Trap-valve**; a clack-valve or flap-valve (see above).
- Turn-valve**; a double-connection valve or gate.
- Underskut valve**; a valve beneath the sole-plate of a pump, etc., and which closes by upward pressure from below.
- Vapor**.—A gaseous form of a substance which ordinarily exists in solid or liquid form, and while it is in this gaseous form it is physically a real gas, which may be defined as a substance which at ordinary temperatures and pressures exists in the gaseous state; hence, all vapors are gases but all gases are not vapors. A *saturated vapor* is a vapor which is on the point of condensation. A *non-saturated vapor* is one which obeys the laws of gases, as superheated steam.
- Variable gear**.—Geared wheels or sectors which impart alternating changes in speed.
- Vault**.—A long arch (not in span but in the direction of the axis), or one whose length is great in proportion to its span. The space enclosed by or beneath such a vault.
- Conical vault**; a vault formed as upon part of the surface of a cone.
- Compound vault**; a vault composed of two or more simple vaults.
- Cross vault**; a vault which crosses another.
- Cylindrical vault**; a vault of cylindrical form.
- Double vault**; a vault placed above or enclosing another vault.
- Elliptical vault**; a vault of elliptical form.
- Groined vault**; a vault formed by two intersecting vaults.
- Pointed vault**; a vault pointed.
- Rampant vault**; a vault which springs from planes not horizontal.
- Simple vault**; an ordinary vault with one axis.
- Single vault**; one vault.
- Spherical vault**; a vault of spherical form.
- Surbased vault**; a circular vault whose height is less than half the span.
- Surmounted vault**; a circular vault whose height is greater than half the span.
- Vaulting-shaft**.—A shaft to receive the spring of a roof-vault rib; may extend downward to the floor or to the capital of a pier.
- Vaulting-tile**.—A tile used in vaulting; hollow and of various forms.
- Vault-light**.—A vault cover set with glass for the admission of light.
- Vault-shell**.—The masonry, skin, plate or thin filling between the ribs of a vault.
- Veneer**.—A thin layer of costly or ornamental wood glued over the surface of a cheaper variety composing the frame.
- Venetian blind**.—A hanging blind operated with cords, the slats being held together by some flexible material.
- Vermicular work**.—The surface of architectural stone so dressed or worked as to appear thickly covered or indented with worm tracks or shapes.
- Vernier**.—A small movable scale sliding parallel with a fixed scale, the number of subdivisions varying by 1, in order to obtain more exact readings; as the vernier of a transit instrument.
- Viaduct**.—A series of (masonry) arches supporting a roadway.
- Viscosity**.—Internal friction in the movement of liquids and gases. **Viscous fluids** are those in which viscosity is strongly present.
- Vise**—**vice**.—A tool with two gripping jaws that may be opened or closed by a screw worked with a lever; used by carpenters and machinists in gripping pieces to be worked.
- Vitreous**.—Resembling glass; glassy.
- Vitrified**.—The whole body, or the surface only, converted into glass glazed, as vitrified- or glazed-brick, tile, terra cotta, pipes, etc. The vitrification is performed by the action of heat.
- Volt**.—The practical unit of electromotive force.

Volt-Ammeter.—A watt-meter.

Volt-Ampere.—A watt.

Volt-Coulomb.—The unit of electrical work. The joule.

Voltage.—Electromotive force or differential of potential.

Voltmeter.—An instrument for measuring the difference of potential.

W.

Wainscot.—A wooden lining or paneling of the walls of a room, and reaching upward three feet or more above the floor.

Wale — **wale-piece.**—A longitudinal timber fastened to a row of piles to keep them more rigid and in position; or fastened along a ship, cofferdam, caisson, wharf, quay, or jetty, etc.

Wall.—In mining, one of the rock surfaces enclosing a vein or lode.

Wallow.—To wobble, as a water-wheel revolving unevenly on its journals.

Wallower — **lantern-wheel.**—See *Lantern-wheel*.

Wall-plate.—In building, a horizontal timber placed on top of the wall to bind it together and stiffen it; and to receive the ends of girders, joists, rafters, roof-trusses, etc., and distribute their pressures over the wall. In mining, the two long pieces of timbers of the four comprising a set of timbering in a shaft.

Warp.—A twist or bend as in a piece of timber which in drying has twisted. A rope smaller than a cable and used in towing or warping a vessel. Sediment.

Warped surface.—A surface which looks as though it had been twisted from a true plane; applies to the surface of boards, stones, soffits of arches, etc.

Warping-bank.—A ridge of earth raised around an area of land for holding water let in to enrich the land with warp or sediment.

Wash-board — **mopboard** — **skirting board.**—A board around the walls of a room next to the floor. A base-board.

Washer.—An annular piece of metal, leather, or rubber, etc., placed at a joint to prevent leakage, or under a nut to distribute pressure, etc. *Flat washers* are stamped out of plate (metal); *cast washers* are thicker and mostly of the O. G. pattern, a section of the edge describing a reversed curve.

Washout.—Excavation of a bank or hillside by the erosive action of water; the cutting or washing away of a road-bed by rains or floods; etc.

Waste-gate.—A gate placed at the waste-outlet of a reservoir, pond, or lake, etc. See *Tide gate*.

Waste-pipe.—A pipe for discharging waste water; an overflow-pipe.

Waste-trap.—A device in a pipe to allow the surplus water to escape and yet prevent gases from returning.

Waterway.—An opening or passage for waste water or overflow.

Waste-weir.—A cut in the side of a reservoir, pond, or canal, etc., for the discharge of surplus water.

Waste-well.—A well into which surplus water is discharged; should have a permeable bed, as gravel.

Water-butt.—A large cask used as a reservoir or tank for water.

Water-craft.—Vessels and boats in general.

Water-float.—A float placed in a tank, boiler, or cistern, etc., to control a valve.

Water-gage.—A device for indicating the height of water in tank, boiler, or reservoir, etc. A connecting glass tube may be used, or a float connected with an indicator, or a board with elevations marked upon it; various contrivances.

Water-gate.—A gateway, gate or valve for controlling the passage of water through an opening or pipe or channel.

Water-hammer.—The impact of water when its volume of flow is checked suddenly as by a gate in a water-pipe; large gates in long pipes are regulated by gearing to close slowly in cases where the combined volume and velocity would tend to produce considerable impact if checked suddenly, pipes often bursting from this cause.

Water-inch.—The quantity of water which will discharge through a circular hole one inch in diameter in 24 hours, the surface of the water being at top of hole; about 500 cubic feet.

Water-main.—One of the main pipes in a system of water-works; the main pipe in each street, or the main pipe supplying several streets, or the main pipe leading from the reservoir or headworks.

- Water-meter.**—An instrument, device or apparatus for measuring the velocity or rate of discharge of water.
- Water-motor.**—A water-wheel or turbine. Any motor deriving its power from the pressure and flow of water, either for direct pumping or for the transmission of power to any kind of machinery.
- Water-pillar = water-crane.**—A vertical pipe with a swinging arm or gooseneck, acting as a sort of hydrant for supplying water to locomotives.
- Water-plane.**—A plane passing through the water line of a ship, i. e., the water-surface plane; hence the terms *light water-plane* and *load water-plane*.
- Water-ram.**—A hydraulic ram, for raising water.
- Watershed.**—The boundary of a *catchment area* or basin, i. e., the high ridge or *divide* which surrounds the area drained by a stream.
- Water-table.**—In architecture, a string-course around the base of a building, and projecting outward for ornament and as if to throw off water from the wall.
- Water-tower.**—A large standpipe.
- Water-tube boiler.**—A form of boiler containing pipes or tubes in which the water circulates, being heated by the surrounding flames.
- Watt.**—The unit of electric power. The volt-ampere. One watt is equivalent to the work of 0.7373 foot-pound per second = $\frac{1}{746}$ horse power.
- Watts = volt-amperes = $CE = C^2R = \frac{E^2}{R}$** , in which *C* = current in amperes, *E* = electromotive force in volts, *R* = resistance in ohms.
- Watt-Meter.**—A galvanometer, for measuring simultaneously, the current and the difference of potential at any point of a circuit.
- Watt-second.**—A unit of electrical work.
- Way-gate.**—The tail-race of a mill.
- Ways.**—The inclined timbers on which a ship moves in launching.
- Weather-boarding.**—A facing of boards on a building; the boards being either (1) clapboards, laid horizontally with feather-edge upward and overlapping each other like shingles, or (2) boards nailed vertically and having either tongued and grooved joints or else narrower boards nailed over the joints, or (3) ordinary shingling.
- Weather-tile.**—Tile used as a substitute for weather-boards.
- Wedge-valve.**—A wedged shaped valve operated by a screw.
- Wedging.**—The process of driving a wedge into a saw-kerf in the end of a tenon which just passes through a through-mortise, in order to expand the end of the tenon and make it bind firmly against the sides of the mortise, as in securing the helve or handle or an ax into the steel head.
- Weir.**—A dam across a stream, over which the water flows. A measuring weir, simply called a *weir* and more properly a *standard weir*, for measuring the flow of water.
- Weld.**—To unite metallic substances by hammering or compression, with or without previous heating; if heated to fusion, a flux is used to prevent oxidation or rapid rusting. Electric welding is accomplished by bringing the proposed joint into a circuit, the greater resistance at the joint causing the abutting surfaces to become intensely hot, and then applying great mechanical pressure.
- Weld-iron.**—Wrought-iron is weld-iron.
- Weld-steel.**—Puddled steel.
- Well-boring.**—The process of sinking or driving wells by drilling or boring through rock, often to great depths; percussion drills are most frequently employed. A form of *well-sinking*.
- Well-trap = sink-trap.**—A trap which allows water to pass down, but prevents air or gases from passing up; such as an S-trap.
- Welt.**—A strip of metal riveted to two abutting plates, forming a butt-joint. Similarly in carpentry, a strip placed over a seam or joint to strengthen it.
- Wharf.**—A platform or depot for vessels. Plural is wharves or wharfs.
- Wheel.**—A circular body or frame revolving on an axis. The wheel and axle, lever, wedge, pulley, screw and inclined plane comprise the six simple machines or mechanical powers.
- Wheel-base.**—The distance between centers of the extreme front and rear wheels of a locomotive, or car, etc.
- Wheel-window.**—In architecture, a special circular window.
- Whitewash.**—(1) common, quicklime and water; (2) good, whiting, size and water.
- Whiting.**—Chalk specially prepared by drying, grinding, etc.

- Wicket.**—A small gate, door or opening in a larger one; a small gate in the lock-gate of a canal, by which the chamber can be emptied; a small gate in a water-wheel chute, etc.
- Winch.**—An axle with one or two bent arms or cranks for turning, as a common windlass or a grindstone. The axis may be geared to a separate drum, thus giving more power for hoisting.
- Wind** [Pronounced with long i].—A turn, twist or bend. *Out of wind* means free from turns, twists, bends, etc.; used in specifications for timber, stone, etc.
- Windage, of Dynamo.**—A term proposed for the air gap between the armature and the pole-pieces of a dynamo.
- Wind-beam—collar-beam.**—A beam joining together the rafters of a pitched roof.
- Wind-bore.**—The end of the suction-pipe of a pump, and covered with a strainer to exclude foreign material.
- Wind-bracing.**—Any system of braces to stiffen a frame against the pressure of the wind.
- Winder.**—One of the steps in a stair where the staircase winds or turns.
- Wind-gage—anemometer.**—An instrument for determining the velocity and pressure of the wind.
- Wind-hatch.**—The opening where ore is taken out of a mine.
- Winding-engine—drawing-engine—hoisting-engine.**—An engine used in turning a drum around which is wound a hoisting- or winding-rope.
- Windlass.**—A large axle bulging into a drum at the center, or a modified wheel and axle, used with a winding rope in hoisting or hauling weight or loads, raising anchors, etc.; the ends of the axle are pierced with radial holes in which handspikes are inserted as levers or cranks in winding, and the drum is fitted with ratchet and pawls. Also operated by steam, as the *steam-windlass*.
- Wing.**—A prefix used with certain names of structures which flare out like a wing.
- Wing-dam.**—A dam projecting out from the shore so as to divert the current; used to deepen channels, protect river-banks from wash, etc.
- Wing-gudgeon.**—A short, winged metal-shaft used as a journal for wheels having wooden axles.
- Wing-wall.**—One of the lateral, flaring walls of an abutment, and acting as a sort of retaining-wall.
- Winze.**—In mining, a vertical or inclined shaft which does not reach the surface but usually connects one level with another, for ventilation, passages, etc.
- Wiper.**—In machinery, a sort of lever-cam attached to a (horizontal) shaft for the purpose of pressing against the toe or projection from another (vertical) shaft and raising it so it may fall again by its own weight; used in connection with marine-engines, stamp-mills, etc.
- Wood-screw.**—A common metal screw for fastening metal or wood to wood. But see *Lag-screw*.
- Work, Unit of Electrical.**—The erg.
- Work, Units of.**—(See pages 90, 91.)
- Working-beam—walking-beam—beam.**—The large beam of a steam-engine, usually the marine or pumping type, and used as an oscillating lever in connecting the piston-rod and crank-shaft or pump-rod.
- Working-point.**—The part of a tool or machine producing the desired effect or work.
- Worm.**—A shaft with a screw-thread which in revolving engages the teeth of a wheel and turns it; the worm is called an endless screw, and the wheel a worm-wheel.
- Wrecking-pump.**—A steam-pump of great capacity used in pumping water from wrecked or damaged vessels.
- Wrench.**—A tool with a lever arm and with jaws for holding or turning pipe, rods, bolts, heads, nuts, etc.
- Wrought-iron.**—Iron that has been forged or rolled, and may be forged, rolled or welded.

Y.

Yard.—A round spar with tapering end or ends. In railroading, the space set aside for handling and making up trains, and general switching; and by extension it includes the space, tracks, buildings, etc., at railway stations.

Yard-limit.—The extreme end of a yard, at which a sign usually cautions extreme care or slower speed in running trains.

Y-level.—Common engineers' spirit-level.

Yoke.—Any sort of a U-shaped strap or coupling.

Yoke, Multiple-Pair Brush.—A device for holding a number of pairs of brushes of a dynamo electric machine in such a manner that they can readily be moved or rotated on the commutator cylinder. Also:

Multiple-pair-brush-, Single-brush-, Single-pair-, Single-pair-brush-, etc.

Y-track.—A Y-shaped arrangement of tracks leading from another track, and often used instead of a turntable in turning engines, cars, or whole trains.

INDEX.

- minutes and seconds to decimals of a degree, table, 1010.
- natural functions of, in the four quadrants, 138.
- of friction for various substances, 517-521.
- of polygon, sum of interior and exterior, 129.
- of quadrilateral, sum of interior and exterior, 128.
- of repose for various substances, 517-521.
- of triangle, sum of interior and exterior, 128.
- rolled, properties of, 538.
- skeleton section, properties of, 530, 531.
- steel,
- properties of, tables, 548-553.
- rivet gages for, 614.

Angle, angles—Cont'd.

- supplement and complement of, 139.

to lay off, (90° , 60° , 45° , 30°), 130.
 ($x = 0^\circ - 360^\circ$), trigonometric values, 139.

($x + y$), trig. values of, 139.

($x - y$), trig. values of, 139.

($\frac{1}{2}x$), trig. values of, 140.

($2x$), trig. values of, 140.

($3x$), trig. values of, 140.

($4x$), trig. values of, 140.

Animals, classification of, 347.

Anions (in electrolysis), 357.

Annealing, steel, 395.

Annuities, various kinds of, 63.

Annuity,

- and sinking fund tables, 64-65.

final value of, formula, 63.

present or initial value of, formula, 63.

Anode pole, 357.

Anthracene, from creosote, 367.

Anti-logarithm,

defined, 104.

of numbers, to find, 105.

Antimony (Sb), 318.

cast, tensile strength of, 496.

minerals, 330.

-tin alloy, tensile strength of, 499.

uses of, 330.

Antiseptic, borax as, 330.

Apex,

of cone, 134.

of pyramid, 133.

Apothecaries'

measure (fluid), metric equivalents, table, 83.

weight, metric equivalents, table, 86.

Apothems of polygon, 129, 204.

 of cast iron pipe and special castings, dimensions, etc., of, tables, 1220, 1221, 1223, 1243, 1245.
 wires, elec. code rules, 1448.
- Belt conveyor, in screening gravel,** 419.
- Belting,**
 cotton, strength of, 512.
 flax, strength of, 512.
 leather, friction of, 517, 518, 519.
- Bending**
 and resting moment of beams, 298.
 extreme fiber, values of concrete in beams, 585.
 in building materials, safe fiber stress, 822.
 modulus of elasticity, of timber, table, 493.
 moments
 and chord stresses, 307.
 and shears for engine loading, table, 692.
 of pins, table, 630.
 problem in, 637.
 strength of metals, table, 496.
 tests of timber, table, 492, 493.
- Bends,**
 in *cordage*, 669.
 in pipe lines, loss of head in, 1160.
- Bents,**
 grass-hopper, 789.
 trestle—, 788-792.
- Bernouilli, lemniscate of, equation of,** 260.
- Beryllium, chem.,** 318.
- Bessemer**
 processes, 394, 395.
 steel, defined, 1487.
- Beton-Coignet, manufacture of,** 417.
- Bevel siding lumber (fir), classified,** 389.
- Binder, asphalt pavement, specifications,** 1110.
- Binomial formula,** 101.
 cube root by, 102.
 square root by, 102.
- Bins and bunkers, reference data,** 1481.
- Birches, classification of,** 344.
- Bismuth (Bi.),** 318.
 alloys, 330.
 minerals, 330.
 tensile strength of, 496.
 uses of, 330.
- Bitolithic pavement**
 patents, 1127.
 specifications, 1105, 1126.
- Bitumastic enamel, coating,** 359.
- Bitumen,**
 described, 404.
 weight of, 478.
- Bituminized-brick,**
 specifications, 1116.
 gutters, specifications, 1115.
- Bituminous**
 and asphalt rock deposits of U. S., 1141.

- Bituminous—Cont'd.
 compounds, grouping of, 1141.
 rock pavement, 1100.
- Black or galvanized pipe, table, 1284.
- Blast-furnace, 392.
- Blasting,
 and drilling in tunneling, 934.
 ballasting-, 923.
 gelatin, 352.
 -holes, drilled with well-driller,
 cost, 926.
 in rock, drill holes for, 922.
 mat, woven, 923.
 powder, composition of, 350.
 stumps, cost data, 916.
 submarine, cost, 925.
- Block, blocks,
 paving, size of, 1129.
 shapes, properties of, 533.
 stone, kinds of, 417.
- Blow-off, blow-offs,
 described, 1280.
 branches,
 cast iron pipe, table, 1230, 1257.
 with manhole, cast iron pipe,
 tables, 1231, 1258.
- Blowpipe characteristics, 328.
- Bluestone,
 composition of, 331.
 defined, 402.
 physical properties of, table, 507.
- Board, boards,
 classification of, 388.
 measure, 379.
 table, 380.
- Booster, defined, 1380.
- Boat,
 drill-, for submarine work, 925.
 spikes, table, 628.
- Bodies,
 falling, table, 283.
 impact effect, 304.
- Boiler, boilers,
 cement, 402.
 staybolts, etc., in, (ref.), 1378.
 plate steel (open hearth), specifications, 501.
 power required for channeling machines, 421.
 steam, 1361-1363.
 efficiency and rating, 1361.
 horse-power of, defined, 1361.
 settings, notes, 1362.
 tests of coal as fuel, table, 1353.
- Boiling-point,
 absolute, defined, 513.
 defined, 513.
 of chemical elements, table, 318.
 of liquids, table, 514.
 of substances, tables, 514.
- Bolsters, for bridges, specifications, 705.
- Bolts
 and nuts, tables, 618-621.
 rail-, 1060.
 standard, for fastenings, 618.
- Bomb colorimeter, described, 1352.
- Bond,
 between concrete and steel, tests (ref.), 585-586.
 English, defined, 437.
 Flemish, defined, 437.
 masonry, defined, 432.
 value of concrete in beams, 585.
 in brickwork, 764.
 of concrete to steel, 823.
- Boneblack for paint, 355.
- Borates, 330.
 in min., classification of, 327.
- Borax, uses of, 330.
- Boron
 chem., 318.
 minerals, 330.
- Borings,
 diamond drill, cost data, 917
 in soil, 866.
 wash drill, cost data, 916.
- Bosses on cast iron pipe, 1280.
- Botanical materials, 340.
- Boulder
 foundation, 865.
 pavement, specifications, 1107.
- Bow's notation for trusses, 309.
- Box-girder,
 steel beam-
 problem, 569.
 properties of, table, 568.
- Boxes,
 gate, table, 1288.
 outlet-, elec. code rules 1429.
 resistance-, elec. code rules, 1449.
 switch-, elec. code rules, 1429.
- Braces, rail-, 1071.
- Bracing,
 lateral-, of bridges, problem, 697.
 portal-, of bridges, 698.
 vertical-, of bridges, 698.
- Brake horsepower (B. H. P.), formula, 1374.
- Branches,
 blow-off,
 cast iron pipe, table, 1230, 1257.
 with manhole, cast iron pipe,
 tables, 1231, 1258.
 hydrant, cast iron pipe, table, 1229.
 pipe, cast iron,
 L's, T's, crosses, table, 1225.
 1250-1254.
 Y's, table, 1227, 1228, 1255.
 1256.
- Brass,
 cast,
 physical properties of, table, 496.
 sheet, wire, etc., weight of, table, 478.
 expansion coefficient of, 516.
 friction of, 518, 519.
 melting point cf, 515.
 table 397.
 wire, physical properties of, 496.
- Brazing-metal, 397.
- Breakers, circuit-, elec. code rules, 1434.
- Breakwaters, 901
 cost data, 902-904.
 materials for concrete of, 904.

 - effect of, on bending moments, 695.
 - end connections of, 700.
 - reactions,
 - Cooper's loading, table, 708.
 - for concentrated loads, table, 694.
 - from electric cars, tables, 717, 718.
 - for highway bridges, table, 728.
- Flooring,
 - classification of, 388.
 - glass, physical properties of, 512.
 - lumber (fir), classified, 389.
- Florin (Dutch), equiv. (1-10-50-100) in U. S. money, table, 97.
- Flotation,
 - depth of, formula, 1152.
 - of bodies, 1152.
- Flour cement, 402.
- Flow
 - in cu. ft. per sec. reduced to horsepower, table, 1833.

- low—Cont'd.
 in open channels, surface and mean velocity of, 1183.
 of air in small pipes, friction formula, 1189.
 of liquids, theory of, 1154.
 of steam
 through pipes formula and table, 1361.
 through orifices, (ref.) 1377.
 of water
 in open channels, diagram, (ref.) 1189.
 in pipes, measurement of, 1183.
 in wood pipes, (ref.) 1187.
 through submerged tubes, (ref.) 1189.
 lowing water, energy of, (ref.) 1188.
 lue boilers, described, 1362.
 luid
 drachm (apoth.), metric equiv., 83.
 measure (apoth.), metric equivalents, table, 83.
 ounce (apoth.), metric equiv., 83.
 lume, flumes,
 and conduits, irrigation, 1317.
 for water supply, 1207.
 measuring-, instructions for installing, (ref.) 1187.
 proportioned for maximum discharge, 1161.
 semicircular, merit of, 1317.
 steel, for water supply, 1207.
 valves, table, 1279.
 luorine, *chem.*, 318.
 lush hydrants, table, 1290.
 lux,
 asphaltic, specifications, 1125.
 borax as, 330.
 lywheel, tension in rim, problem, 297.
 locus (*pl. foci*)
 of ellipse, 258.
 of parabola, 258.
 oot,
 cord (wood), metric equiv., 82.
 cubic,
 equivalents, 67.
 metric equivalents, 68, 82.
 decimals of, to inches and fractions, table, 223.
 equivalents, 68.
 metric equivalent of, 66, 68.
 pounds
 and meter-kilograms, equiv., 89.
 equivalents of, 90.
 table, 91.
 per hour, equivalents of, 90.
 per minute, equivalents of, 90.
 per second, equivalents of, 90.
 square, metric equivalents, 68, 81.
 valves, vertical, table, 1279.
 ootings, foundation-, 867, 868.
 orce and motion, equations of, *mech.*, 278.
 orce, forces,
 centrifugal, 297.
 component, 305.
 defined, 278.
 Force, forces,—Cont'd.
 distributed-,
 center of gravity of, 296.
 resultant of, 296.
 electromotive, defined, 1382.
 equations of, in mechanics, 288, 289.
 equilibrium of, in *mech.*, 294.
 lines of, electric, defined, 1382.
 outer and inner, in structures, 305.
 parallel, center of gravity of, 295.
 parallelogram of, 294.
 polygons, 295.
 at joints of truss, 310.
 resolution of, 294.
 tractive problem, 288.
 triangle of, 294.
 unbalanced, formulas, 288.
 Foreign
 coins and paper notes, equiv. (1-10,-50-100) in U. S. money, tables, 96-97.
 money, tables, 95-97.
 weights and measures, American equivalents, table, 92-94.
 Forest stumpage in the U. S. 376.
 Forgings,
 carbon and nickel steel, chemical properties of, 505.
 nickel steel, physical properties of, table, 499.
 steel,
 physical properties of, table, 499.
 specifications, 505.
 testing, 506.
 Forms for concrete, costs, (ref.) 1293.
 Foundation, foundations, 863.
 beds,
 bearing pressures, 863-865.
 classification of, 863.
 coffer-dams for, 869.
 concrete, 867.
 footings, 867, 868.
 for buildings, 819.
 gravel and sand, 864, 865.
 hard-pan, 864.
 I-beam, 867.
 indurated clay, 864, 865.
 loads, for buildings, 866.
 loads on, estimating, 866.
 loam, 865.
 of dams, pressure on, 848-851.
 pile, 871.
 pneumatic, 880.
 references, 890.
 road specifications, 1101.
 sand-, 864, 865.
 sewer, 1306.
 sheet piling for, 869.
 soils,
 bearing power of, for buildings, 867.
 tests of, 865.
 solid rock, 863, 864.
 spread-, reinforced concrete, (ref.) 890.
 sub-,
 concrete for, 442.
 cement grout injected in, 442.
 walls, waterproofing for, 418.

- Foundry work, 392.
 Fountain, aerating-, in reservoir 1206.
 Fractions
 and decimals, short methods of multiplication and division, 11-13.
 kinds of, 7.
 reduced to decimals, tables, 9-10.
 reduction of, 7-10
 (12ths) reduced to decimals table, 9.
 (64ths) reduced to decimals, table, 10.
 Fractional distillation of gasoline, table, 1376.
 Franc (French), equiv. (1-10, -50-100) in U. S. money, table, 97.
 Francis' weir formulas, 1178.
 Freezing
 mixtures, 513.
 point, defined, 513.
 point of liquids, table, 514.
 process, in foundation work, 882.
 test for sandstone, 402.
 weather, laying masonry in, 433.
 French
 money, U. S. values, 95.
 thermal unit (Cal.) defined, 1347.
 Frequencies and voltages, in *elec.*, 1470.
 Friction, 517.
 angle of, for various substances, tables, 517-521.
 head, in pipe lines, 1160.
 heads in cast iron pipe, table, 1217.
 in machines, table, 521.
 laws of, 517.
 losses in pipes, defined, 1161.
 Morin's experiments, 517.
 of air in small pipes, formulas, 1189.
 of journals on their pillows, table, 520.
 of plane surfaces, table, 517.
 of various substances, table, 521.
 rolling, 521.
 sliding, 517-521.
 sliding-, of train, 702.
 Frictional resistance of cylinder piers, 878.
 Frictionless orifices, experiments on, (ref.) 1187.
 Frog, frogs, 1075.
 and switches, tables, 1079-1082.
 angles, properties of, table, 1076.
 crossing-, 1078.
 kinds of, 1075.
 manganese steel, 1075.
 movable-point, 1076.
 number, formula, 1075.
 spacing
 on crossover tracks, table, 1089.
 on ladder tracks, table, 1089.
 spring rail, 1075.
 Frost boxes for gate valves, table, 1288.
 Fruhling suction dredge, (ref.) 932.
 Frustum
 of circular spindle, 254.
 of cone, 248.
 defined, 134.
 of conic wedge, 249.
 of cylinder or prism, area, volume, 244.
 of parabolic spindle, 254.
 of pyramid, 248.
 defined, 134.
 Fteley and Stearns' weir formulas, 1180, 1181.
 Fuel, fuels,
 chemical analysis of, 1350.
 heat of combustion of, calculations, 1352.
 heating power of, 1359.
 liquid, properties of, 1370.
 solid, chemical composition of, table, 1352.
 vaporization of, 1371.
 wood as, value of, 1363.
 Fuller's earth, uses of, 331.
 Fulminate of mercury for percussion, 352.
 Fungus in timber, 359.
 Furlong, equivalents, 68.

 brick, 415.
 pipe, for water supply, 1207.
- Glucinum**, *chem.*, 318.
- Glue**,
 cement, 402.
 marine, (ref.) 418.
- Gneiss**,
 and granite, weights of, 475.
 composition of, table, 336.
 compression tests of, 511.
 compressive strength of, 511.
 defined, 340.
 transverse strength of, 511.
- Gold**,
 cast,
 physical properties of, 497.
 etc., weight of, 480.
chem., 319.
 -copper alloy, tensile strength of, 497.
 dredging, 930, 932.
 melting point of, 515.
 minerals, ores, 328.
 plating, 358.
 wire, tensile strength of, 497.
- Gondola cars**, large capacity, (ref.) 1091.
- Gothic sewers and conduits**, properties of, table, 1303.
- Government land surveying**, 967.
- Grade**, grades,
 angles
 and % of, equivalents, table, 1002.
 and rates per mile, equivalents, table, 1003.
 cost of haul on, table, 996.
 economic considerations, 992.
 feet per 100 ft. and per mile, tables, 1001, 1003.
 limiting-, 992.
 locomotive traction on, 992.
 problem, 993.
 table, 994.
 of large irrigating canals, table, 1317.
 of sewers, 1296.
 of tunnels, 935.
 on profiles, railroad, 1004.
 reduction (R. R.), allowable expense for, 995.
 ruling-, 992.
 determination of, 996.
 traction on, 1097.
- Grader**, elevating-, used in railroad excavation, cost data, 916.
- Gradients**, railroad-, 991.
- Grading**,
 for street pavement, specifications, 1127.
 lumber, 387.
 railroad, economic problem, 269.
 with wheeled scrapers, cost data, 917.
- Grain**, grains,
 and grams, equiv. (1-10), table, 85.
 (apoth.) metric equivalent, 86.
 (avoir.), metric equivalents, 86.
 metric equivalents, 68.
 troy,
 equivalents, 67.
 metric equivalents, 86.
- Gram**, grams,
 and grains, equiv. (1-10), table, 85.
 and ounces,
 equivalents, 89.
 equivalents (1-10), table, 85.
 English equivalents, 68, 85.
 per cu. centimeter and pounds per cu. in., equivalents, 89.
 standard, equivalents, 67.
- Granite**,
 block pavement,
 described, 1100.
 specifications, 1102, 1105, 1119.
 block paving, specifications, 1105.
 building, 400.
 composition of, 331.
 table, 337.
 compression tests of, 511.
 compressive strength of, 511.
 excavation, in open cuts (R. R.), cost, 925.
 expansion coefficient of, 516.
 heat effect on, 400.
 high compression tests, 511.
 kinds of, 400.
 paving blocks, 1102.
 properties of, 400.
 temperature stress for 160° F., 523.
 tension tests, (ref.) 511.
 transverse strength of, 511.
 weight of, table, 475.
- Graphical**
 methods, in *struc.*, 306, 310.
 solution
 of catenary, 753.
 of Pratt truss, 312.
 of truss, 310.
- Graphite**,
 for paint, 355.
 paint, 359.
 weight of, 480.
- Grashof's analysis of flat plates** (ref.) 586.
- Grasshopper bents**, 789.
- Gravel**
 and composition filling for wood block pavement, specifications, 1128.
 foundation, 864, 865.
 friction of, 521.
 quarrying, 419.
 roads,
 application of oils to, 1134.
 construction of, 1098.
 screening, 419.
 sidewalks, construction of, 1098.
 streets, oiled, specifications, 1114.
 swellage when loosened, 911.
 voids in, 911.
 concrete, 416.
 weight of, 475.

Graving dock, 892.
 Gravity
 acceleration,
 formula, 459.
 equation of, 287.
 table, 283.
 center of, of trapezoid, 847.
 force of, 278.
 specific, (see specific gravity).
 yards, (ref.) 1091.
 Gray iron castings, specifications, 498.
 Great-circle,
 arc of, defined, 135.
 of sphere, defined, 134
 Greensand, 337.
 use of, 340.
 Greenstone,
 composition of, 338.
 properties of, 400.
 trap, weight of, 480.
 Greatest common factor, to find, 6.
 Groined arch in filter and reservoir construction, (ref.) 1292.
 Gross,
 equivalent of, 95.
 great-, equivalent of, 95.
 Grounding low-potential circuits,
 elec. code rules, 1401.
 Ground-slope quantities,
 formulas for, 1030.
 correction table, 1039, 1041.
 Grout,
 cement, in sub-foundation, 442.
 filling,
 for wood block pavement, specifications, 1128.
 in brick paving, 1109.
 Grubbing and clearing, 906.
 cost data, 916.
 reference data, 920.
 Guard rails,
 specifications, 700.
 timber, 789.
 Gum
 trees, classification of, 345.
 arabic, weight of, 480.
 Guncotton
 explosives, 351, 352.
 manufacture of, 351.
 Gunmetal, bronze,
 weight of, 478, 480.
 physical properties of, table, 497.
 Gunpowder, 350.
 weight of, 480.
 Gusset plates, 705.
 Guttapercha,
 expansion coefficient of, 516.
 weight of, 480.
 Gutters,
 bituminized-brick, specifications, 1115.
 cobblestone, 1099.
 concrete, specifications, 1111.
 plank, described, 1098.
 Gypsum, 329, 404.
 defined, 339.
 variety of, 336.
 weight of, 480.

Gyraton,
 center of, 303.
 radius of, problem in, 637.
 Gyroscope, theory of, (ref.) 1095.

H

H
 columns, properties of, tables, 608.
 skeleton section, properties of, 530.
 Halite, composition of, 336.
 Hammer-drill, 422.
 Hammers, stone, described, 426-7.
 Hanger boards for series arc lamps,
 elec. code rules, 1442.
 Hardpan
 excavation, by use of dynamite, 923.
 foundation, 864.
 Harlem River ship canal, cost data, 1329.
 Harveyized steel 396.
 Haskell current-meter, 1185.
 Haul,
 earthwork-, 1059.
 on various grades (R. R.), cost of, table, 996.
 Hawser, in cordage, 668.
 Head, heads,
 curvature-, in pipe lines, 1160.
 entry-, defined, 1160.
 friction-, in pipe lines, 1160.
 of eye-bars, added length formula, 686.
 of water,
 for given pressures, table, 1147.
 reduced to equivalent velocities, table, 1155.
 reduced to equivalent pressures, tables, 1148, 1149.
 pressure-, in pipe lines, 1160.
 various hydraulic, defined, 1160.
 velocity-, in pipe lines, 1160.
 Header, masonry, defined, 432.
 Heading
 and drift methods of tunneling, 933.
 in tunneling, defined, 933.
 Heaped bushel, measure of, 84.
 Heat,
 and power, problems, 1350.
 as energy, 1346.
 conductivity and resistance of materials, table, 1377.
 effect
 on building materials, 523.
 on concrete, 510.
 on various substances, 512.
 engines (internal combustion),
 tests of, on alcohol fuel, 1368-1370, 1374.
 equivalent
 of external work, formula, 1356.
 of internal work, formula, 1355.
 expansion by, 516.
 mechanical
 and electrical units, equivalents, table, 91.

- Heat,—Cont'd.
 mechanical—Cont'd.
 equivalent of,
 defined, 1347.
 equiv. (1-10), table, 1349.
 of combustion
 of fuel, calculations, 1352.
 of liquid fuels, 1370, 1375.
 of the liquid, formula, 1355.
 of vaporization, formulas, 1355, 1356.
 resistance,
 and conductivity of materials,
 table, 1377.
 coefficients of, 1377.
 units,
 defined, 1347.
 equivalents of, table, 91.
 equivalents (1-10), table, 1348.
 per sq. ft. per minute, equivalents, table, 91.
 waves, 1380.
- Heaters, electric-, elec. code rules, 1407.
- Heating
 and ventilation, reference data, 1482.
 power of fuels, 1350.
 values of coals, tables, 1350, 1351.
- Heavy oil (creosote), 367.
- Hectar, hectares,
 and quarter section, equiv., 88.
 and township, equivalents, 88.
 English equivalents, 68.
- Hectogram, English equivalents, 85.
- Hectoliter, hectoliters,
 and bushels (U. S.), equiv. (1-10), table, 84.
 English equivalents, 81, 82, 84.
 (francs per) and dollars per bushel,
 equivalents (1-10), table, 98.
 (Germ. marks per) and dollars per
 bushel, equiv. (1-10), table, 98.
 per hectar and bushels per acre,
 equivalents (1-10), table, 84.
- Hectometer,
 English equivalents, 70.
 square, English equivalents, 79.
- Height, slant-, defined, 133.
- Helical springs, formulas, 1482.
- Helium,
chem., 319.
 gas never been liquified, 513.
- Helix or screw, 260.
- Hemlock, hemlocks,
 classification of, 342.
 grading rules, 388, 390.
- Hemp,
 friction of, 518, 519.
 required per joint of cast iron pipe,
 1216.
- Heptagon,
 defined, 129.
 mensuration of, 204.
- Herschel's weir formula, 1181.
- Hertzian ray, 316.
- Hessellmann process for timber, 361.
- Hexagon,
 defined, 129.
- Hexagon,—Cont'd.
 hollow-, properties of, 527.
 inscribed in circle, 131.
 mensuration of, 204.
 regular-, properties of, 526.
- Hexahedron, defined, 132.
- Hickories, classification of, 343.
- Highway, highways, 1097.
 bridges, 720.
 combination-, with details, 729.
 live load data for, 728.
 nickel and carbon steel, specifications, 737; table, 738.
 references, 739.
 typical loading for, 727.
 unit stress sheets, 720.
 with solid floors, weight of,
 formulas, 686.
 with wooden floors, weight of,
 formulas, 686.
- History (Natural) of materials, 316.
- Hitches and knots, in *cordage*, 668-9.
- Hogshead (liquid), equivalents, 83.
- Hoisting,
 rope, tension in, 290.
 work formula, 290.
- Hollow
 circle, properties of, 528;
 concrete blocks, safe loads on, 829.
 ellipse, properties of, 529.
 hexagon, properties of, 527.
 octagon, properties of, 527.
 rectangle, properties of, 525.
 square,
 diagonal axis, properties of, 526.
 properties of, 526.
 tile partitions, 813.
- Hook
 bolts, 618.
 fastenings for wire rope, 675.
 gage, 1182, 1183.
- Horizon, of celestial sphere, defined, 201.
- Horizontal check valves, table, 1278.
- Horse, power of a, 1097.
- Horsepower,
 brake-, (B. H. P.), formula, 1374.
 electric,
 energy value of, 90, 91.
 equivalents of, 90.
 table, 91.
 from flow of one cu. ft. per sec.,
 table, 1333.
- hours,
 equivalents of, table, 91.
 from storage of one acre-ft.,
 table, 1335.
 from storage of 1,000,000 cu. ft.,
 table, 1334.
- indicated, (I. H. P.), formula, 1375.
- mechanical, equivalents of, 90.
 metric, equivalents of, 90.
 of locomotives, problem, 291.
 of steam boiler, defined, 1361.
 of turbines, theoretic, formula,
 1344.
 unit, 291.
- Hose, effect of long lengths of, on
 fire streams, (ref.) 1187.

- Hour
 angle, of a star, defined, 202.
 circle, of celestial sphere, defined, 202.
 or degree, decimals of, for minutes and seconds, 1010.
 (time) and degrees (longitude), equivalents, 99.
- House, houses,
 car-, elec. code rules, 1421.
 drainage, 1295.
 paints, 356.
- Howe truss
 and details, 711.
 brace problem, 635.
- Human body, weight of, 480.
- Hundred weight (avoir.), metric equivalent, 86.
- Hydrant, hydrants,
 branches, cast iron pipe, table, 1229.
 described, 1288.
 Ludlow, weight of, table, 1290.
 nomenclature, 1289.
- Hydraulic, hydraulics, 1154.
 cements, described, 404.
 dredges, 928, 931.
 fill dams, cost data, 919.
 formulas, 1161.
 Basin's, 1189.
 Chezy's, 1167.
 Kutter's, 1167.
 grade line, 1159.
 lime, manufacture and use of, 404.
 limestone, properties of, 401.
 mean radii of pipes, table, 246-7.
 measurements, 1182.
 of streams, (ref.) 1187.
 method of earth excavation, 908.
 notation, 1154.
 problems, 1167, 1172, 1219, 1298, 1306.
 properties of conduits and sewers, tables, 1296-1306.
 shield used in sewer tunnel, cost data, 916.
- Hydrocarbons,
 in *min.*, classification of, 328.
 natural, classification of, 1141.
- Hydrodynamics, defined, 1154.
- Hydro-electric problem, 1379.
- Hydrogen,
 boiling point of, 514.
chem., 319.
 corpuscles in, 316.
 melting point of, 515.
 minerals, 330.
 •-oxygen flame, 317.
 physical properties of, table, 514.
- Hydrokinetics, 1154.
- Hydrometers, 461, 462.
- Hydrostatics, 1145.
 head and pressure,
 equiv. (1-10), 1146.
 tables, 1146-1149.
 pressure,
 for lead pipe, 679.
 formulas, 1146.
- Hydrostatics,—Cont'd.
 pressure,—Cont'd.
 in pipes and tanks, 1152.
 on dams, 845.
 on submerged surfaces, 846, 847.
 units, 1146.
- Hydroxide, in *chem.*, defined, 321.
- Hyperbola,
 equation of, 259.
 normal to, 259.
 tangent to, 259.
 equilateral, 260.
- Hyperbolic
 logarithms, defined, 104.
 example in, 106.
 table, 108.
 spiral, equation of, 260.
- I
- I,
 block, properties of, 533, 534.
 skeleton section, properties of, 530, 531.
- I-beam, -beams,
 block, properties of, 533, 534.
 cast separators for, table, 623.
 rivet gages for, 614.
 skeleton, properties of, 530, 531.
 special, properties of, table, 584.
 standard connection angles for, 615.
 steel, properties of, 554.
- Ice,
 evaporation from, 1199.
 expansion coefficient of, 516.
 hard, compressive strength, 512.
 melting point of, 515.
 weight of, 480.
- Icosahedron, defined, 132.
- Impact,
 coefficient of, for bridges, table, 709.
 effect of, 489.
 formulas, 303.
 railroad bridges, effect of, 701.
- Impedance and inductance in transmission line, 1387, 1392.
- Impulse
 and momentum, 293.
 water wheels, 1336.
- Ion, positive and negative, 317.
- Incandescent lamps, in series circuits, elec. code rules, 1406.
- Inch, inches,
 and centimeters,
 cubic,
 equivalents (1-10), table, 82.
 equivalents, 88.
 equivalents (1-10), table, 70.
 equivalents, 88.
 square,
 equivalents (1-10), table, 80.
 equivalents, 88
 and millimeters,
 cubic, equiv. (1-10), table 82.
 equivalents (1-10), table, 70.
 square, equiv. (1-10), table, 80.

Inch, inches,—Cont'd.

- cubic,
 - equivalents, 67.
 - metric equivalents, 68, 82.
- decimals of, to millimeters, table, 69.
- equivalents, 68.
- fractions of,
 - and millimeters, equivalents, 88.
 - to decimals and millimeters, table, 69.
- metric equivalent of, 66, 68.
- miner's, table, 1313.
- pounds and centimeter-grams, equivalents, 89.
- square, metric equivalents, 68, 81.
- to decimals of a foot, table, 223.
- (1-12) to meters, equiv., table, 71.

Inclined

- plane,
 - in *mech.*, formula, 292.
 - motion on, 286.
 - velocities on, 286.
- railway, (ref.) 1091.

Increasers,

- cast iron pipe, tables, 1233, 1259-1264.

Matheson pipe, table, 1281.

India rubber, weight of, 480.

Indicated horsepower (I. H. P.), formula, 1375.

Indium, *chem.*, 319.

Inductance and impedance, in transmission line, 1387, 1392.

Induction, electric, defined, 1381.

Inductive load, in *elec.*, 1453.

Inelastic bodies, impact effect, 304.

Inertia,

- moment of,
 - about inclined axis, formulas, 535-538.
 - about parallel axis, 524.
 - of rectangles, table, 539-540.
 - of rolled shapes, 537.
- polar moment of, 535-538.
- maximum and minimum values, 537.

Infusorial earth, uses of, 331.

Insect larvæ in timber, 359.

Inspection of yellow pine lumber, 387, 388.

Insulated wires, table, 1423.

Insulating joints, elec. code rules, 1442.

Insulation,

electrical, 1462.

resistance,

elec. code rules, 1396.

tables, 1447, 1450.

Intake, mouthpiece (bell-shaped) at, 1177.

Integral calculus, 272.

Integration,

definite, 273.

double, for polar moment of inertia, 535, 536.

formulas for, 274, 275

method of using current meters, 1186.

Interest,

compound,

methods, 59-62.

table, 62.

simple,

common and exact methods, 58-59.

table, 60.

Interior conduits, elec. code rules, 1412, 1450; table, 1428.

Interlocking plant, railroad, (ref.) 1093.

Internal combustion engines, tests of, on alcohol fuel, 1368-1370, 1374.

Intersection of curves, to find, 102.

Intrados of arch, curve of, 764.

Inverse trigonometric functions, 140.

Iodides, in *min.*, classification of, 325.

Iodine, *chem.*, 319.

Ions, in electrolysis, 357.

Iridium,

chem., 319.

minerals, 328.

-platinum, expansion coefficient of, 516.

Iron,

chem., 319.

cast,

expansion coefficient of, 516.

for buildings, 819.

melting point of, 515.

pipe, 1214.

physical properties of, table, 497.

properties of, 392.

temperature stress for 160° F., 523.

weight of, 480.

cement, 402.

(ref.) 418.

corrosion of, in concrete, (ref.) 455.

friction of, 518, 519.

gray, castings, specifications, 498.

in buildings, stresses for, 824.

malleable cast,

high tensile strength of, 398.

tensile strength of, 497.

melting point of, 394.

minerals, ores, 329.

molten, weight of, 480.

ore,

treatment of, 392.

uses of, 329.

oxide(s)

for paint, 355.

paints for iron and steel, 373.

physical properties of, table, 497

pig,

manufacture of, 392.

uses of, 392.

pipe,

cast, specifications, 1239.

wrought, 1268.

preservation of, 358.

slag block pavement, specifications, 1121.

vitreous fusion of, 515.

weight of, 480.

wire, physical properties of, 498.

Iron.—Cont'd.

- wrought,
 - expansion coefficient of, 516.
 - for buildings, 819
 - in buildings, safe stresses, 826.
 - manufacture of, 393.
 - melting point of, 515.

 equiv. (1-10), English and metric,
 table, 70.
 metric and English, equivalents,
 table, 88.
 of curves, by calculus, 275.
 of spans, economic, 683.
 units of, equivalents, 66.
- Lentinus lepidens, in timber, 362.

- Level,**
adjustment of, 941.
sections, earthwork, list of tables, 1017.
- Leveling,** 987.
allowable errors in, table, 989.
correction for earth's curvature and refraction, 987.
sources of errors in, 987.
- Levelman,** duties of, in preliminary survey (R. R.), 1004.
- Lever,**
compound, formulas, 292.
simple, formulas, 291.
- Leverage,** in *mech.*, formulas, 291.
- Libra** (Philippine weight), English equivalents, 81.
- Light-waves,** 1380.
- Lights, signal,** elec. code rules, 1450.
- Lighting,**
and electric power, 1379.
electric-, cost data, table, 1478.
systems, decorative-, elec. code rules, 1414.
- Lightning arresters,** elec. code rules, 1396, 1444.
- Lignite,** weight of, 480.
- Lignum vitæ** journals, friction of, 520.
- Lime,**
(cement), properties of, 403.
(common,) properties of, 403.
fat, 403.
hydraulic, manufacture and use, 404.
mortar, 403.
for brickwork, 403.
for buildings, 819.
weight of, 475.
plaster, 403.
quick-, 403.
slacked, 403.
specific gravity of, 403
weight of, table, 475.
- Limestone,**
building, 400.
composition of, table, 335.
compressive
strength of, 511.
tests of, 511.
defined, 339.
formation of, table, 335.
hydraulic properties of, 401.
in *min.*, 329.
kinds of, 401.
properties of, 400.
quarrying, 419.
tensile strength of, 511.
tension tests, (ref.) 511.
transverse strength of, 511.
travertine 401.
weights, of, table, 475.
- Limnoria,** in timber, 360.
- Line, lines,**
and angles, geometric, definitions, 128.
of force, electric, defined, 1382.
of resistance of masonry arches, 768.
pole-, elec. code rules, 1400.
- Line, lines,—Cont'd.**
right-, projection of, 262, 263.
skeleton-, properties of, 529, 531.
straight-,
defined, 132.
equation of, 256.
intersection with circle, solution, 257.
transmission-, 1386.
- Linea** (Philippine measure), English equivalent, 81.
- Lining,**
reservoir, 1206.
tunnels, 934, 939.
- Link**
-fuse cut-outs, elec. code rules, 1434.
fuses, elec. code rules, 1436.
surveyor's, equivalents, 68.
- Linseed oil,**
boiling point of, 514.
for iron and steel, 372.
for steel, 358.
manufacture and use, 356.
weight of, 480.
- Lintels,** for buildings, requirements of, 820.
- Live load** data for highway bridges, table, 728.
- Liquefaction** of gases, how accomplished, 513.
- Liquid, liquids,**
and dry capacities, metric and English equivalents, table, 88.
boiling point of, table, 514.
capacities,
equivalents, 67.
equiv. (1-10), English and metric, table, 83.
metric, English equiv., table, 82.
defined, 512.
freezing point of, 514.
gallons (U. S.) and liters, equivalents (1-10), table, 83.
measure, English (U. S.), metric equivalents, table, 83.
ounces and milliliters (c.c.) equivalents (1-10), table, 83.
physical properties of, table, 514.
quarts (U. S.) and liters, equivalents (1-10), table, 83.
specific gravities of,
table, 468, 469.
to find, 461.
weights of, table, 468, 469.
- Lira** (Italian), equiv. (1-10, -50-100) in U. S. money, table, 97.
- Liter, liters,**
and barrels (liquid), equiv., 88.
and gallons
(U. S.), equivalents, 88.
(U. S. liquid), equiv. (1-10), table, 83.
and pecks (U. S.), equiv. (1-10), table, 84.
and quarts
(U. S.), equivalents, 88.
(U. S. liquid), equiv. (1-10), table, 83.

Liter, liters.—Cont'd.

- English equivalents, 68, 81, 82, 84.
- (francs per) and dollars per gallon, equivalents (1-10), table, 98.
- (German marks per) and dollars per gal., equiv. (1-10), table, 98.
- of water, weight of, 67.
- per minute (discharge), equiv., 90.
- standard, equivalents, 66.

Lithium,
chem., 319.
minerals, 328.

Lithology, 331.

Live loads on floors and roofs, table, 815.

Load, loads,
data for highway bridges, table, 728.

factor, in *elec.*, 1453.

floor-, for buildings, 820.

from safes, 816.

 residuums, test properties, 1134.
- Petrolithic pavement, specifications,
 1112.
- Pewter, 398.
 expansion coefficient of, 516.
 weight of, 480.
- Phase, single-, alternator, defined,
 1384.
- Philippines, weights and measures,
 English equivalents, 81.
- Philorier's mixture or freezing, 513.
- Phoenix columns, properties and
 safe loads, tables, 604, 605.
- Phosphates, in *min.*, classification
 of, 327.
- Phosphor bronze, 397.
 physical properties of, table, 497.
- Phosphorus, *chem.*, 319.
 weight of, 480.
- Photometry and lamps, in *elec.*, 1473.
- Pi (π),
 circular measure, 99.
 table of combinations of, with logs,
 205, 206.
 times any number, tables, 224-
 229.
- Pick, stone-, described, 428.
- Pickling, for mill scale, 358.
- Pie (Philippine measure), English
 equivalents, 81.
- Pier, piers,
 concrete pile, for steamship termi-
 nal, (ref.) 900.
 construction, 893.
 crib, 877.
 cylinder, 878.
 frictional resistance of, 878.
 docks and wharves, 892.
 masonry, 888.
 contents of, 889.
 pile, 877.
 platform cylinder, 879.
 pneumatic cylinder, 879.
 reinforced concrete. (ref.) 890.
 river, 889.
 steel, in Africa, (ref.) 900.
 tubular, 877.
- Pierhead and bulkhead lines, 892.
- Piezometer tubes, 1174.
- Pig iron,
 manufacture of, 392.
 use of, 392.
- Pigments for paints, 355.
- Pile, piles,
 -and-timber trestles, 790.
 bearing power of, 819.
 in various materials, 890.
 concrete, 875.
 creosote in, analysis of, 370.
 cutting off, 874.
 dead-men-, 874.
 disk, 874.
 drivers, 871.
 derrick, 873.
 drop-hammer, 872.
 portable, 873.
 power for, 873.
 steam-hammer, 872.
 tilting-, (ref.) 890.
- driving,
 formulas, 871.
 water jet in, 873.
- false, 788.
- fender-, 893.
- foundations, 871.
- iron, 874.
- maximum load on, 787.
- metal-shell, concrete, 875.
- piers, 877.
 concrete, for steamship terminal,
 (ref.) 900.
 planted, 874.
- pulling machines, (ref.) 871.
- reinforced concrete, 875.
- safe bearing power of, table, 872.
- sand, 875.
- screw, 874.
- shoes, 874.
- supporting power of, 871.

- Pile, piles.—Cont'd.
 spacing and driving, 874.
 spliced, 874.
 trestles, 877.
 water-jet concrete, 875.
- Piling,
 cost of creosoting, 860.
 preservation of, 860.
 sheet-, 869.
- Pillars, (see Columns).
- Pilot-nuts, 629.
- Pin, pins,
 bending moments of, table, 630.
 bending stresses on, specifications,
 704.
 bridge-, 629.
 cotter-, 629.
 lateral-, 629.
 -nuts, table, 629.
 plates, for bridges, 706.
 steel-, properties of, table, 630.
- Pine, pines,
 expansion coefficient of, 516.
 classification of, 341.
- Pint,
 (apoth), metric equivalents, 83.
 (dry), metric equivalent, 84.
 (liquid), metric equivalent, 83.
 metric equivalents, 68.
- Pipe, pipes,
 or butt (liquid), equivalents, 83.
 and tubes, 677.

- Plenum process, 879.
- Plug, plugs,
 and feathers, described, 426.
 cast iron pipe, tables, 1234, 1267.
 Metheson pipe, table, 1281.
- Plumbago, weight of, 481.
- Pneumatic
 caissons, 880.
 caulking of mains with lead wool,
 costs, (ref.) 1293.
 cylinder piers, 879.
 foundations, 880.
 process, 879.
 stone-dressing machine, (ref.) 430.
- Point,
 stone-, described, 428.
 (the), projection of, 262.
- Pointing, masonry,
 defined, 432.
 specifications, 434.
- Polar
 distance,
 of a circle, defined, 135.
 of a star, defined, 202.
 of Polaris for latitude 0°, 949.
 moment of inertia, 535-538.
 maximum and minimum values, 537.
- Polaris,
 azimuth of,
 at elongation, 950.
 tables, 954-955f.
 how to find, 948.
 observations of, 951.
 for azimuth, 949.
 polar distances of, for latitude 0°, table, 949.
 time of upper culmination of, table 953.
 to determine meridian from, 948.
- Pole, poles,
 concrete telegraph, 1477.
 cost of creosoting, 374.
 (geom.) of a circle, defined, 134.
 iron, 373.

- Pole, poles,—Cont'd.**
 lines, elec. code rules, 1400.
 of celestial sphere, defined, 201.
 preservation of, 373.
 reinforced concrete, (ref.) 1142.
 wooden,
 for electric line, 373.
 life of, 373.
- Polygon, polygons,**
 definitions of, 129.
 (general), properties of, 129.
 of forces, 295.
 regular,
 area of, 129.
 formulas and table, 204.
 properties of, 129.
- Polyhedrons,**
 (geom.), 132.
 regular, table, 243.
- Polyphase alternator, defined, 1384.**
- Poplars, classification of, 343.**
- Population of cities in U. S., 1202.**
- Porcelain, expansion coefficient of, 516.**
- Porch decking lumber (fir), classified, 389.**

 average monthly, in U. S., table, 1191.
 data most useful to engineers, 1190.
 distribution of, 1190.
 high intensities of, formulas, 1195-1197.
 in U. S., for driest years, 1194, 1195.
 relation of, to runoff, in California, (ref.) 1201.
Rain-gage, standard, 1196.
Rain-water, weight of, 482.
Randoms, in *surv.*, correction of, 976.
Random-work masonry, defined, 432.
Range-work masonry, defined, 432.
Rankine's theory of earth pressure, 839-840.
Ransome stone, manufacture of, 417.
Rapid sand filtration, 1204.
Rating,
 electrical, 1454.
 pitot-tube, (ref.) 1189.
Ratio and proportion, 55-56.
Rattler test for bricks, 507, 1116.
Reaction, reactions, and moments, 295.
breakwater, 905.
drawbridge-, tables, 744, 745, 747.
floorbeam-,
 for concentrated loads, table, 694.
 for highway bridges, table, 728.
 from electric cars, tables, 717, 718.
 in *struc.*, in any direction, 314.
 of forces, 295.
 to find, 305.
Reactive
 coils and condensers, elec. code rules, 1443.
 -factor, in *elec.*, 1453.
Ream, paper measure, 95.
Reaming, in bridge work, 706.
Reciprocals,
 by slide rule, 126.
 common tables, 51-54.
 engineers' tables, 28-29.
 powers and roots of numbers, 14-54.
 to find, 30.
Reconnaissance survey, (R. R.), 998.
Rectangle, rectangles,
 angular axis, properties of, 525.
 area and cen. of grav., 203.
 axis at base, properties of, 525.
 defined, 128.
 diagonal axis, properties of, 525.
 hollow-, properties of, 525.
 moments of inertia of, table, 539-540.
 properties of, 525.
 skeleton section, properties of, 530.
Rectangular
 beams,
 formulas, 563.
 loads on, table, 566.
 cell, skeleton, properties of, 530.

Rectangular—Cont'd.
 conduits, proportioned for maximum discharge, 1161.
 orifices, center of pressure on, formulas, 1151.
Red
 heart, in lumber, defined, 387.
 lead
 for paint, 355.
 paint, 359.
 weight of, 481.
 oxide for paint, 355.
 rays, length of, 1380.
Reducers,
 cast iron pipe, tables, 1233, 1259-1264.
 Matheson pipe, table, 1281.
Redwoods, classification of, 342.
Refraction,
 defined, 1520.
 and curvature, table, 988.
Refuse disposal, 1295.
 miscellaneous data, (ref.) 1309-1312.
Regenerative method of liquefying gases, 513.
Register current-meter, 1186.
Regulation, electrical-, 1461.
Reinforced concrete, 443.
 aqueduct, 1208.
 arch bridges, cost of, 784.
 arches, reference data, 784.
 beam, beams,
 diagram, (ref.) 586.
 formulas, 444, 447.
 table, 446.
 tests, formulas, (ref.) 585.
 Thatcher's computation, 585.
 time element effect in loading, (ref.) 586.
 working stresses, 585.
 bridges,
 highway, cost data, 738.
 railroad, 712.
 piers, (ref.) 890.
 buildings, unit stresses used, 831.
 caissons, for breakwaters, 904.
 columns,
 formulas, 449.
 working stresses for, 609.
 construction,
 building regulations for, by Nat'l Assn. of Cem. Users, 831.
 for buildings, 822, 834.
 design, office methods, (ref.) 455.
 economic design of, (ref.) 585.
 flat plates, methods of computing (ref.) 586.
 floors, instruction sheet for placing, (ref.) 586.
 formulas of A. S. C. E., 446.
 French Gov't rules, (ref.) 454.
 in buildings, references, 830-834.
 jetty-head, (ref.) 905.
 members separately-molded, cost data, (ref.) 831.
 piles, 875.
 poles, (ref.) 1142.
 proportions of mix, 444.

- Reinforced concrete,—Cont'd.
 references, 456.
 retaining walls, (ref.) 841-843.
 roadway base, (ref.) 1112.
 slabs, slide rule for, (ref.) 586.
 T-beam and column tests, (ref.) 586.
 trestles, 792.
 use of, (ref.) 455.
 wharf, (ref.) 900.
- Reinforcement, steel, in beams, tensile stress value, 585.
- Relief valves, pressure-, described, 1288.
- Reluctance, magnetic-, formula, 1520.
- Repeated stresses, defined, 487.
- Reports and valuations, expert, reference data, 1484.
- Repose, angle of, for various substances, 517-521.
- Reservoir, reservoirs, 1205.
 aerating fountain in, 1206.
 concrete expansion joints in, 454.
 distributing, 1205.
 linings, 1206.
 miscellaneous data, (ref.) 1291-1294.
 outlet pipe from, how arranged, 1205.
 storage-, 1205.
 walls, waterproofing for, 418.
 waterproofing, 1293.
- Residuums from refining crude oil, 1133.
- Resilience, 488.
 elastic, defined, 488.
 formulas, 488.
 modulus of, defined, 488.
- Resin,
 a tree product, 346.
 defined, 481.
 mastic, weight of, 480.
 weight of, 481.
- Resistance
 boxes, elec. code rules, 1395, 1449.
 electric-, formula, 1520.
 insulation-, elec. code rules, tables, 1447, 1450.
 line of, of masonry arches, 768.
 of materials, 486.
- Resisting
 and bending moment of beams, 296.
 moments, problem in, 637.
 forces, in *mech.*, 294.
- Resultant
 of a distributed force, 296.
 of two velocities, 284.
 velocities, 284.
- Restitution, coefficient of, 304.
- Retaining
 plank, street, specifications, 1111.
 stone, street, specifications, 1109.
 walls, 835.
 dimensions of, table, 842.
 dry, specifications, 435.
 masonry, specifications, 434.
 quantities in, table, 841.
 reference data, 841-843.
 standard type, 841.
- Return wires, elec. code rules, 1406.
- Reversed curves, (R. R.), 1012.
- Revetments, reference data, 1481.
- Revolved planes, 261, 262, 265.
- Rheostats, elec. code rules, 1398, 1442.
- Rhodium, *chem.*, 319.
- Rhomboid,
 defined, 129.
 area and cen. of grav., 203.
 properties of, 525.
- Rhombus,
 defined, 129.
 and area, 203.
- Rhyolite,
 composition of, table, 338.
 defined, 340.
 formation of, table, 338.
- Right
 angle, circular and time measure, equivalents, 99.
 ascension, of a star, defined, 202.
 -of-way,
 purchase and condemnation, 1014.
 railroad-, 1013.
 required widths of, table, 1014.
 tables, 1014, 1015.
- Ring, rings,
 circular,
 mensuration of, 219.
 moment of inertia of, 302.
 segmental, mensuration of, 253.
 collector-, defined, 1383.
 regular circular, mensuration of, 253.
 revolving, tension in, 297.
- Riprap, quarrying, 419.
- Rise of temperature, in *elec.*, 1466.
- River, rivers,
 mean velocity depth of thread in, 1187.
 spans, economic layout of, 683.
- Rivet, rivets, 611.
 button head, 616.
 countersunk, 616.
 gages for standard steel shapes, table, 614.
 shearing and bearing values, table, 612.
 signs, Osborn code, 611.
 spacing and clearance of, table, 613.
 weights and dimensions of, table, 616.
- Riveted
 joints,
 application of polar moment of inertia to, (ref) 538.
 net areas of, table, 617.
 problem, 612.
 spiral-, steel pipe, 680-682, 1269.
 steel pipe, design of, 1268.
 work, in bridges, specifications, 706.
- Rivet-steel,
 extra soft, specifications, 502.
 fire-box, specifications, 502.
 flange or boiler, specifications, 502.

- Rivet-steel,—Cont'd.
 open hearth, specifications, 501.
 test pieces, 502.
 testing, 502.
- Road, roads,
 and streets, 1098.
 application of oils to, 1134.
 construction, use of tar in, 1132.
 corduroy, described, 1098.
 dirt-, described, 1098.
 dust preventives, experiments,
 costs, 1136.
 gravel-, construction of, 1098.
 graveled, oiled, specifications, 1114.
 macadam
 and telford, specifications, 1111.
 specifications, 1116.
 oils for,
 best kinds, 1133.
 classification of, 1133.
 properties of, 1133.
 oiling, cost, (ref.) 1142.
 plank, described, 1098.
 sampittic surfacing of, (ref.) 1142.
 specifications, 1101.
 surfaces,
 application of oils to, 1134.
 application of tars to, 1132.
 care of, 1131.
 dust preventives, 1131.
 tars for, 1131.
 traction on, 1097.
 surfacing materials, tests of, table,
 1144.
 tar macadam, cost, 1142.
- Roadbed, standard-, (R. R.), 1059.
- Roadway,
 board bed, specifications, 1128.
 concrete base, specifications, 1102,
 1109.
 crushed-stone base, specifications,
 1105.
 gravel base, specifications, 1102.
 macadam, specifications, 1105,
 1129.
 reinforced concrete base, (ref.) 1112.
- Rock, rocks,
 -asphalt, experiments on roads,
 costs, 1138, 1139.
 -breaking machines, for rock ex-
 cavation, (ref.) 926.
 calcareous, 400.
 cementing material in, table, 334.
 common,,
 notes on, 339.
 table, 334.
 crushed, voids in, 911.
 crushers, capacity, cost, etc., 439.
 crystal (halite), weight of, 481.
 crystalline, siliceous, 400.
 cuts,
 open-, excavation of, 922.
 side slopes for, 922.
 drills, 922.
 in quarrying, 422.
 Little Giant, 425.
 percussion,
 dimensions, etc., table, 424.
 weights, etc., table, 424.
- Rock, rocks,—Cont'd.
 excavation, 922.
 by channeling machines, 924.
 by Lobnitz rock breaker and
 other machines, (ref.) 926.
 Chicago canal, 924.
 costs, 925.
 methods, 925.
 Panama canal, cost data, 919.
 -fill dams, quantities in, table, 857.
 formations, 331.
 fragmentary, 401.
 granite, excavation, in open cuts,
 (R. R.), cost, 925.
 loading on cars, by steam shovel,
 924.
 loose, classification (R. R.), 919.
 loosened, voids in, 911.
 salt, composition of, 336.
 solid,
 classification (R. R.), 919.
 foundation, 863, 864.
 swellage when broken, table, 911.
 trench excavation, estimating, 923.
 trenching in, 923.
- Rod, rods,
 and meters,
 equivalents, 88.
 square, equivalents, 88.
 counter-, 634.
 equivalents, 68.
 floats, for hydraulic measurements,
 1183.
 or bar, moment of inertia of, 302.
 square, metric equivalent, 81.
 steel,
 areas and weights, table, 542.
 weights and areas, table, 542.
- Rolled
 angle, properties of, 538.
 channel, properties of, 537.
 T-beam, properties of, 537.
 tee, properties of, 538.
 shapes, properties of, 535-538.
 Z-bar, properties of, 538.
- Rollers, segmental-, table, 635.
- Rolling
 brick pavement, 1107.
 friction, 521.
- Roman
 numerals, table 1.
 system of numbers, 1.
- Röntgen ray, 316.
- Road, metric equivalent, 81.
- Roof, roofs, 794.
 angles and pitches of, table, 796,
 797.
 coverings, 798.
 live loads
 for, 824.
 on, table, 815.
 pitches and angles of, tables, 796,
 797.
 reference data, 811.
 snow loads on, 797, 798.
 tile-, specifications, 800.
 trusses,
 combination-, design of, 806-
 810.

- Roof, roofs.—Cont'd.
 trusses.—Cont'd.
 four cases, 314.
 stress diagrams
 for, 803-804.
 of, 314, 315.
 timber for, 819.
 types of, 803.
 unit stresses in, tables, 804, 805.
 weight of steel in, 810, 811.
 wind pressure on, tables, 796, 797.
- Roofing,
 asphalt-gravel, 802.
 cement-gravel, 802.
 corrugated steel, 801.
 materials, 798.
 weight of, table, 802.
 patented, 802.
 sheet-steel-, 801.
 shingle, 799.
 slag-, 802.
 slate,
 laying of, 402.
 tables, 799, 800.
 tar-gravel, 801.
 tile, 800.
 tin-, 800.
- Root, roots,
 and division, algebraic, 102.
 by slide rule, 126.
 cube,
 engineers' tables, 21-24.
 to find, 20.
 of decimals, by logarithms, 106.
 of numbers, by logarithms, 106.
 powers and reciprocals of num-
 bers, 14-54.
 square
 and cube, common tables, 31-
 50.
 engineers' tables, 16-19.
 of fifth powers, engineers' table,
 25.
 to find, 14.
- Rope,
 hoisting, tension in, 290.
 in *cordage*, 668.
 manila, 669.
 weight and strength of, tables,
 669-670.
 tension in traction, 289.
 wire-, 673.
 fastenings, 675.
 tables, 674.
- Rosendale cement (see, also, Ce-
 ment, natural),
 manufacture of, 404.
- Rose's fusible metal, melting point
 of, 515.
- Rosettes, elec. code rules, 1439.
- Rosin,
 a tree product, 346.
 defined, 481.
 weight of, 481.
- Rosseau's hydrometer, 461.
- Rot, in lumber, defined, 387.
- Rotary
 furnace, for cement making, 405
 pumps, 1367.
- Rotating machines, electrical-, defi-
 nitions, 1451.
- Rotting of timber, 359.
- Rough
 edge (lumber), classification of,
 388.
 lumber (fir), classified, 389.
- Roughness *N*, values of, 1168.
- Rubber
 -covered wire, tables, 1424.
 India, weight of, 480.
 vulcanizer, 330.
- Rubble
 concrete dam, 860.
 masonry, defined, 432.
 stonework, in buildings, safe loads
 for, 821.
- Rubidium, *chem.*, 319.
- Ruble (Russian, gold), equivalents
 (1-10,-50-100) in U. S. money,
 table, 97.
- Rueping process, for ties, cost, 375.
- Runoff,
 distribution of, 1190.
 formulas for, 1197, 1198.
 in storm sewers, formulas, dia-
 grams and tables, (ref.) 1310.
 relation of rainfall to, (ref.) 1201.
 relation of, to rainfall, in Califor-
 nia, (ref.) 1201.
- Rupture (bending) tests of timber.
 table, 492.
- Russian money, U. S. values, 95.
- Rustic lumber (fir), classified, 389.
- Rutgen's process, for timber, 361.
- Ruthenium, *chem.*, 319.

S

- S-trap, 1295.
- Sabin process for pipe coating, 358.
- Safes,
 loads from, 816, 817.
 weight of, table, 816.
- Safety factor,
 defined, 487.
 for timber, 496.
 in building, 821.
- Salt,
 a, in *chem.*, defined, 321.
 and ice for freezing, 513.
 solutions, as road dust prevent-
 ives, 1131.
 (rock), composition of, 336.
 weights of, table, 481.
- Saltpetre, weight of, 481.
- Samarium, *chem.*, 319.
- Sampittic surfacing of roads, (ref.)
 1142.
- Sand
 -blast
 cleaning
 and painting, 373.
 (ref.) 374.
 with cost, 374.
 for mill scale, 358.
 bricks, manufacture of, 417.
 filtration of water, methods, 1204.
 foundation, 864, 865.

- Sand,—Cont'd.
 impurities in, for concrete, (ref.) 455.
 Ottawa, in cement testing, 409.
 piles, 875.
 quarrying, 419.
 sieve in cement testing, 409.
 standard, in cement testing, 409.
 voids in, 911.
 concrete, 416.
 weight of, table, 476.
- Sandstone,
 best kind of, 401.
 building, 401.
 block pavement, specifications, 1124.
 blocks, paving, specifications, 1124.
 composition of, 331.
 table, 334.
 compression tests of, 512.
 compressive strength of, 512.
 defined, 339.
 expansion coefficient of, 516.
 formation of, table, 334.
 freezing test, 402.
 frost action on, 401.
 kinds of, 401.
 physical properties of, 512.
 quarrying, 419.
 temperature stress for 160° F., 523.
 tensile strength of, 512.
 test for frost action, 402.
 transverse strength of, 512.
 water absorbed by, 401.
 weight of, 476.
- Sanitary
 disposal, miscellaneous data, (ref.) 1309-1312.
 works, designs, (ref.) 1311, 1312.
- Sanitation, 1295.
- Saturated steam,
 formulas, 1355.
 tables, 1355-1360.
- Saturation-factor, in *elec.*, 1453.
- Saturization of earth dams, 860.
- Sault Ste. Marie canals, data, 1322.
- Saws, lumber, kinds of, 379.
- Sawing
 logs, 379.
 lumber, 379.
- Scalene triangle, defined, 128.
- Scaling logs, 379.
 (ref.) 391.
- Scandium., *chem.*, 819.
- Scantling,
 classification of, 388.
 lumber (fir), classified, 389.

properties and tables of, 541.
Shear, shears,
and web stresses, 307.
and moments for engine loading, table, 692.
end-,
Cooper's loading, table, 708.
for highway bridges, table, 728.
from electric cars, tables, 717, 719.
in beams and girders, various loadings, 688.
in building materials, safe stresses, 822.
in *struc.*, method of, 306.
in trusses, various loadings, 693.
longitudinal, in beams, formula, 565.
-steel, 395.
Shearing
effect on columns, 587.
strengths of metals, table, 496.
tests of timber, with grain, 494.
values of concrete in beams, 584.
Sheet, sheets,
asphalt pavement, specificat., 1110.
lead, 679.
metal,
weight of, from specific gravity, table, 484.
gages, tables, 667.
paper measure, 95.
piling, 869.
steel, 870.
Sheeting, corrugated, strength of, (ref.) 561.
Shield,
hydraulic-, used in sewer, *manol.*, cost data, 916.
method of tunneling, 934.
Shims, track-, thickness of, 1069.
Shingle, shingles,
dimensions of, 390.
grading of, 390.
roofing, 799.
wooden, table, 799.

- Shipping weights of lumber, 391.
- Shoes,
cast-, for wood stave pipe, 1209.
pile-, 874.
- Shop drawings for structural steel,
cost of, 665.
- Shrinkage,
earthwork, reference data, 920.
in earth dams, 914.
- of earth, 909.
 how estimated, 910-913.
 fills, recommendations, 914.
of earthwork,
 experiments, 913.
 railroad specifications for, 913.
vertical in earth embankments, 915.
- Shroud laid, in *cordage*, 668.
- Sidereal
and mean solar time, equivalents,
 table, 202.
day, defined, 202.
- Sidewalk, sidewalks,
areas, surfacing, 1115.
brick, specifications, 1103.
cement,
 described, 1099.
 specifications, 1117.
concrete,
 specifications, 1111, 1129.
 base for, specifications, 1129.
crushed-stone, specifications, 1105.
gravel, construction of, 1098.
part cement, part gravel, 1115.
plank-, described, 1098.
practice in Chicago, costs, 1143.
- Sienite, composition of, 337.
- Sin *na* for paint, 355.
 e, sand-, in cement testing, 409.
 signs,
 angular and time measure, equivalents, 99.
electrical notation, 1471.
values (trig.), 137.
- Sil lights, elec. code rules, 1450.
- Sig aling systems, elec. code rules,
 1444.
- Sili
 erals, 331.
 weight of, 481.
- Silicates,
in *min.*, classification of, 326.
most important, 331.
- Silicic acid, weight of, 481.
- Silico *tem.*, 319.
-br 397.
 te... strength of, 497.
-wire as conductor, compared
 with copper, 497.
- Sills, wooden trestle, 788.
- Silver, *hem.*, 320.
cast tensile strength of, 498.
ex on coefficient of, 516.
melting point of, 515.
minerals, ores, 328.
weight of, 481.
- Simple
and compound units, equivalents,
 table, 88.
interest tables, 60.
- Simultaneous equations,
examples in, 103.
graphical, 256.
- Sine, sines,
logarithmic, table, 176-198.
natural, table, 144-166.
(trig.), defined, 136.
- Single-phase alternator, defined,
 1384.
- Sinking fund, 63.
and annuity tables, 64-65.
formula, 65.
diagrams and tables, (ref.) 1293.

concrete, calculation of, (ref.) 455.
floor-, reinforced concrete, bending
 moment, 823, 825, 827, 829,
 832.
reinforced concrete,
 slide rule for, (ref.), 586.
 Thacher's computation, 585.
- Slag
block pavement specifications,
 1121.
cement, manufacture of, 404.
roofing, 802.
weight of, 481.
- Slant height, defined, 133.
- Slate,
composition of, 331.
table, 334.
defined, 339.
expansion coefficient of, 516.
formation of, table, 334.
formed how, 402.
physical properties of, 512.
quarried where, 402.
roofing, 402, 799.
temperature stress for 160° F.,
 523.
weight of, 477.
- Sleeve, sleeves,
cast iron pipe, tables, 1232, 1265.
nuts, 634.
weights and dimensions, table,
 633.
- Slide
rules,
described, 126-127.
problems, 126-127.
for reinforced concrete slabs, (ref.)
 586.
-valve engines, performance of,
 1365.
- Sliding friction, 517-521.
- Slip,
in cement making, 405.
of rods in concrete beams, (ref.)
 455.
- Slope
and deflection of beams, formulas,
 562.
artesian-, defined, 1190.
side-, for rock cuts, 922.
-stakeing, 1055.
walls, dry, specifications, 436.

- Slow
 sand filtration, 12^m.
 -burning wire in *vacuum*, table, 1425.
 Sludge, defined, 1525.
 Sluice gate, -gates, stand and wheel, 1270. table, 1279.
 Slurry, in cement making, 405.
 Smelting, 357.
 Smith's durable metal coating, 358.
 Smokeless powders, 352.
 Snap switches, elec. code rules, 1433.
 Snow,
 evaporation from, 1199.
 loads on roofs, 797, 798.
 weight of, 481.
 Soapstone, 340.
 weight of, 481.
 Sockets,
 elec. code rules, 1413, 1440, 1450.
 fastenings for wire rope, 675.
 Sodium, *chem.*, 320.
 chloride, use of, 340.
 minerals, 328.
 Soil, soils,
 bearing capacity of, 819.
 bearing power of, for buildings, 867.
 borings in, 866.
 defined, 909.
 density of, 909.
 for foundation, tests of, 865.
 pipes, 1295.
 seepage in, various, 1200.
 Solar
 and sidereal time, equivalents, table, 202.
 attachment, 944.
 adjustment of, 947.
 day, defined, 202.
 ephemeris tables, reference to, 202.
 instrument, uses of, 946.
 observations with transit alone, 947.
 power, reference data, 1484.
 Solder, 398.
 kinds of, 1525.
 Soldering fluid, elec. code formula, 1447.
 Solid, solids,
 center of gravity of, 302.
 coefficient of expansion of, table, 516.
 defined, 512.
 determining specific gravity of, 460.
 Geometry, 182-135.
 melting points of, 515.
 mensuration of, 243.
 moments of inertia of, table, 302.
 radius of gyration of, 302.
 rock classification (*R. R.*), 919.
 Solvents, cement, 402.
 Sorel stone, manufacture of, 417.
 South point, of celestial sphere, defined, 201.
 Space,
 Analytic Geometry of, 256.
 in *mech.*, defined, 278.
 Spans, bridge-, economic length of, 683.
 Spandrel, parabolic, properties of, 237, 529.
 Spar, weights of, 481.
 Spark arresters, elec. code rules, 1442.
 Sparkling distances, in *elec.*, 1474.
 Specials,
 pipe, described, 1290.
 pipe-castings, bells of, dimensions, etc., tables, 1221, 1223, 1243, 1245.
 Specific
 gravity, gravities,
 by displacement method, 460.
 defined, 460.
 equivalents for any weight, table 474.
 methods for determining, 460.
 of brick, table, 474.
 of building stones, table, 474.
 of cement by LaChatelier's apparatus, 407.
 of granular substances, to find, 461.
 of liquids, table, 468, 469.
 of materials, 459.
 general table, 478.
 of porous substances, to find, 460.
 of tars, 1132.
 of woods, table, 470-473.
 reduced to weight, table, 483, 484.
 standards for determining, 460.
 heat of the liquid, formula, 1356.
 volume
 of saturated steam, defined, 1356.
 of the water, formula, 1356.
 Specifications (see specific items).
 Specifications and contracts, reference data, 1484.
 Spelter, weight of, 481.
 Sphere, spheres,
 area great circle of, equivalents, 250.
 area of surface of, by calculus, 276.
 Celestial, elements of, 201-202.
 circumference of, equivalents, 251.
 cylinder (max.) inscribed in, 269.
 diameter of, equivalents, 251.
 diameter
 (ft. and ins.)
 to surface (sq. ft.), table, 234, 235.
 to volume (in ft.), table, 234, 235.
 (in fractions) to surface (in decimals), table, 226-229.
 to surface,
 in decimals, table, 224, 225, 232, 233.
 in inches, table, 230, 231.
 to volume,
 in decimals, table, 232, 233.
 in inches, table, 230, 231.
 geometry of, 134-135.
 hollow, mensuration of, 253.
 moment of inertia of, 302.

- Sphere, spheres.**—Cont'd.
 properties of, 249.
 radius of, equivalents, 251.
 relations of area, diameter, surface, volume, etc., 250.
 relations to cone, cube and cylinder, 250.
 surface measure, in radii, 135.
 surface of,
 equivalents, 250.
 table, 251.
 tables listed, 251.
 volume of,
 equivalents, 250.
 measure, in radii, 135.
 table, 252.
 tables listed, 252.
 wind pressure on, 797.
- Spherical**
 cone, defined, 135.
 pyramid,
 defined, 135.
 solution of, 199.
 segment,
 defined, 135.
 mensuration of, 252.
 triangles, solution of, 199-201.
 trigonometry, 199-202.
 zone,
 area of, by calculus, 276.
 mensuration of, 253.
- Spindle,**
 circular, mensuration of, 253.
 cycloidal, mensuration of, 254.
 oil, weight of, 481.
 parabolic, mensuration of, 254.
- Spikes,**
 railway,
 effect of creosote oil on, 361.
 weight per mile of track, table, 1068.
 steel, weights and dimensions, tables, 626-628.
 street railway, table, 628.
- Spiral,**
 common, 260.
 curves (R. R.), 1013.
 hyperbolic, equation of, 260.
 logarithmic, equation of, 260.
 of Archimedes, equation, 260.
 riveted steel pipe, 680-682, 1269.

 metal-, formulas, 1482.
 steel,
 physical properties of, 499, 1884.
 tests of, table, 1484.
- Spruce, spruces,**
 classificatic f, 341.
 grading rules, 338, 390.
- Square, squares,**
 acreage, dimensions of, 1313.
 and circle, inscribed and circumscribed, 131.
 and cubes, tables of, uses, 636.
 and cube roots, by slide rule, 126.
 axis at base, properties of, 526.
 cell, skeleton, properties of, 530.
 centimeters, English equiv., 79.
 cubes and roots, common tables, 31-43.
 decimeter, English equiv., 79.
 dekameter, English equiv., 79.
 diagonal axis, properties of, 526.
 feet and meters, equivalents, 88.
 foot, metric equivalent, 81.
 yards and meters, equivalents, 88.
 geometric, defined, 128.
 hectometer, English equiv., 79.
 hollow-,
 properties of, 526.
 diagonal axis, properties of, 526.
 inch, inches,
 metric equivalent, 81.
 and centimeters, equivalents, 88.
 kilometers, English equiv., 79.
 land measure, English, metric equivalents, table, 81.
 measure, metric, English equivalent, table, 79.
 mensuration of, 203.
 meter, English equivalents, 79.
 miles and hectars, equivalents, 88.
 mile, metric equivalent, 81.
 millimeter, English equiv., 79.
 mils and millimeters, equiv., 88.
 myriameter, English equiv., 79.
 properties of, 525.
 rod, metric equivalent, 81.
 rods and meters, equivalents, 88.
 root, roots,
 and cube roots, common tables, 31-50.
 by binomial formula, 102.
 engineers' tables, 16-19.
 of fifth powers, engineers' tables, 25.
 to find, 14.
 skeleton section, properties of, 530.
 tables of, for structural detailing, 643-664.
 yard, metric equivalent, 81.

 T-rails for, (ref.) 1142.
 trackway (steel), experimental, cost, 1142.
 Strength
 of materials, 486.
 ultimate, defined, 487.
 Stress, stresses,
 alternating, defined, 487.
 Stress, stresses.—Cont'd.
 chord- and bending moments, 307.
 combined-, tests, (ref.) 522.
 defined, 486.
 -diagrams
 for drawbridge, 746.
 general rules, 310.
 of Pratt truss, 312, 313.
 of roof trusses, 803-804.
 effect of,
 on elastic limit, 487.
 on ultimate strength, 487.
 in beams, formula, 299.
 in structures, theory of, 305
 per area, metric and English equiv table, 89.
 repeated, defined, 487.
 static, defined, 487.
 ultimate, defined, 487.
 unit-, in roof trusses, tables, 804, 805.
 web-, and shears, 307.
 working-,
 defined, 487.
 for reinforced concrete beams, 585.
 Stretcher, masonry, defined, 432.
 Striking the arch center, 773.
 String, in *cordage*, 668.
 Stringers,
 bridge-,
 moments and shears, various loadings, 788.
 spacing of, 700.
 wooden-,
 bending moments, table, 791.
 cast separators for, 623.
 floor-, 789.
 Strontium, *chem.*, 320.
 Struck bushel, metric equiv., 84.
 Structural
 details 611.
 references, 665.
 steel,
 shop drawings for, cost of, 665.
 specifications, 500.
 Structures, theory of stresses in, 305.
 Struts, see Columns.
 Stub switches, 1078.
 Stumpage, forest,
 Pacific Coast, 377.
 U. S., 376.
 Stumps, blasting, cost data, 916.
 Subaqueous concrete, placing, 440.
 Sub-grade shaping, road specifications, 1101.
 Submarine drilling and blasting, cost, 925.
 Submerged
 beams, formulas for pressure and moments in, (ref.) 1189.
 planes, pressure on, 846, 847.
 tubes, flow of water through, (ref.) 1189.
 weirs, 1181.
 formulas, 1181.
 Subscript abbreviation of a decimal 95.

Sub-surface floats, for hydraulic measurements, 1183.
 Subtraction and addition, in algebra, 100.
 Subway excavation, cost data, 916.
 Successive differentiation, 271.
 Sudden loading, effect of, 489.
 Suez canal,
 dimensions and cost, 1320.
 traffic data, table, 1321.
 Sulphates, in *min.*, classification of, 327.
 Sulphides, in *min.*, classification of, 325.
 Sulphur, *chem.*, 320.
 melting point of, 515.
 minerals, 330.
 uses of, 330.
 weight of, 481.
 Sulphuric acid, weight of, 481.
 Superheated steam,
 formulas, 1355.
 in locomotive boilers, use of, (ref.) 1378.
 Superintendence of work, value of good, 908.
 Supplement and complement of an angle, 139.
 Supplementary angles, defined, 128.
 Surface, surfaces,
 curved-, areas of, by calculus, 276.
 floats, for hydraulic measurements, 1183.
 of sphere, measure of, in radii, 135.
 Surfacing, road specifications, 1101.
 Survey, surveys,
 location, (R. R.), 1004.
 preliminary, (R. R.), 1000.
 reconnaissance, (R. R.), 998.
 stadia-, cost data, 990.
 traverse, 964.
 Surveying,
 city-lot, 966.
 farm-, 964.
 Government land, 967.
 instruments, care of, 941.
 mapping and leveling, 941.
 stadia-, 983.
 Surveyors' measure, lineal, metric equivalents, table, 68.
 Suspension
 bridges, 750.
 anchorages of, 755, 759.
 cables vs. chains, 754.
 details and specifications, 756-760.
 miscellaneous data, 760.
 towers and backstays, 754.
 weights of materials in, tables, 758.
 cables, curves of, 750.
 Swedge bolts, 618.
 Sweet gums (trees), classification of, 345.
 Swellage
 of earth, how estimated, 910-913.
 of rock when broken, table, 911.
 Swing bridges, 742.

Switch, switches,
 and frogs, tables, 1079-1082.
 and turnouts, 1075.
 boxes, elec. code rules, 1429.
 elec. code rules, 1404, 1407, 1431, 1449.
 split-, 1084, 1088.
 turnouts for, tables, 1085-1088.
 stub-, 1078.
 table for laying out, 1078.
 ties, bills for, tables, 1070.
 Wharton, 1088.
 Switchboards, elec. code rules, 1395, 1449.
 Swivel hook fastenings for wire rope, 675.
 Syenite, composition of, 337.
 Symbols, atomic, table, 818.
 System, artesian-, defined, 1190.

 Turbine, turbines,
 efficiencies of, 1343.
 horsepower of, theoretic, 1344.
 losses of energy in, 1343.
 nomenclature of, 1342.
 water wheels, described, 1342.
 Turnbuckle, turnbuckles,
 fastenings for wire rope, 675.
 weights and dimensions, table, 633.
 Turnout, turnouts,
 and switches, 1075.
 curves, formulas, 1083.
 for split switches, tables, 1085-1088.
 from curved track, 1084.
 Turntable pit, (ref.) 1093.
 Turpentine,
 a tree product, 346.
 boiling point of, 514.
 for paint, 356.
 oil of, melting point, 515.
 weight of, 481.
 Tweddell's hydrometer, 461.
 Type metal, cast, weight of, 481.

U

Ultimate
 analysis of fuels, 1350.
 strength, defined, 487.
 stress, defined, 487.
 Ultra-violet rays, length of, 1380.
 Umber for paint, 355.
 Undecagon, mensuration of, 204.
 Underground conductors, elec. code rules, 1404.
 Undershot wheel, described, 1336.
 Ungula (circular cylindric-), 244.
 Uniform motion, equations of, 278, 279.
 Unit, units,
 equivalents, simple and compound, table, 88-91.

Unit, units,—Cont'd.
 heat (B. T. U.), equivalents of, table, 91.
 heat, mechanical and electrical, equivalents, table, 91.
 heat, per sq. ft. per minute, equiv. table, 91.
 of electric power, 1379.
 of power, defined, 291.
 stresses in roof trusses, tables, 804, 805.
 of U. S. money, 95.
 United States
 equivalents of foreign weights and measures, tables, 92-94.
 money, 95.
 Upset screw ends, table, 634.
 Urine, weight of, 481.
 Uranite, radium from, 330.
 Uranium, *chem.*, 320.
 in steel, 330.
 minerals, ore, 330.
 weight of, 481.

V

Vacuum process, 879.
 Valency, 318.
 Valuations and reports, expert, reference data, 1484.
 Valve, valves,
 air, 1270.
 and gates, Ludlow, tables, 1274-1279, 1286, 1287.
 boxes, table, 1288.
 Chapman, with wedge-shaped gate, nomenclature, 1285.
 flume-, table, 1279.
 gate-, 1271-1279, 1285-1287.
 described, 1288.
 dimensions and weights of, 1273.
 vertical, geared and ungeared, 1273.
 horizontal check, table, 1278.
 kinds of, 1533.
 Ludlow, nomenclature, 1272.
 -metal, 397.
 pressure relief, described, 1288.
 vertical
 check, table, 1279.
 foot, table, 1279.
 Waring's check, 1296.
 water, 1271-1279, 1285-1287.
 Vanadium, *chem.*, 320.
 -steel, 396, 399.
 alloys, 399.
 Vapor,
 defined, 1534.
 pressure of saturation for liquids, 1372; table, 1373.
 Vaporization,
 latent heat of, defined, 513.
 of fuel, 1371.
 Vaporizers for liquid fuels, 1371.
 Vara,
 (Philippine measure), English equivalent, 81.
 (Texas land measure), English equivalent, 81.

Vara,—Cont'd.
 square (Texas land measure), English equivalents, 81.
Variables, dependent-, defined, 256.
Variation and pulsation, in *elec.*, 1453.
Varnishes, 357.
Vaults,
 fixed-, loads from, 817.
 kinds of, 1534.
Velocity, velocities,
 and discharge
 in pipes, theoretic, table, 1155.
 of sewers and conduits, tables, 1296-1306.
 coefficient of, 1175.
 during impact, 304.
 head in pipe lines, 1160.
 in circular brick sewers, table, 1299.
 in egg-shaped sewers, table, 1305.
 in irrigation canals, 1317.
 in *mech.*, defined, 278.
 mean-, depth of thread of, in rivers, 1187.
 metric and English equivalents, table, 89.
 of approach, 1159.
 in weirs, how measured, 1177.
 of falling bodies,
 from various heights, table, 1155.
 table, 283.
 on inclined plane, 286.
 resultant of, 284.
 surface and mean, in open channels, 1183.
Ventilation
 and heating, reference data, 1482.
 of tunnels, 935.
Venturi meter, 1173.
 measurement of water, 1182.
 standard proportions, 1175.
 (625 cu. ft. per sec.) in India, (ref.) 1189.
Verdigris for paint, 355.
Vermillion, 329.
Vernal equinox, defined, 202.
Versed sines,
 natural, table, 144-166.
 (trig.), defined, 136.
Vertical
 angles, defined, 128.
 bracing, of bridges, 698.
 check valves, table, 1279.
 circle, of celestial sphere, defined, 201.
 curves, parabolic, 1005.
 foot valves, table, 1279.
 line, of celestial sphere, defined, 201.
Viaduct, reinforced concrete, 793.
Vibration of pendulum, 287.
Vicat needle test of cement, 408.
Violet rays, length of, 1380.
Vitreous fusion of glass and iron, 515.
Vitrified brick, 415.
 pavement, specifications, 1121, 1123.

Voids,
 determined for concrete, 440.
 in concrete, formula, 1118.
 in earth, 910.
 in gravel, 911.
 in loam, 911.
 in loosened earth and rock, 911.
 in sand, 911.
Volt, as a pressure unit, 1379.
Voltages and frequencies, in *elec.*, 1470.
Volume, volumes,
 capacities and weights, equiv. (1-9), table, 485.
 critical, defined, 513.
 cu. yds., of pipes, table, 246-247.
 defined, 460.
 equivalents (1-10), English and metric, tables, 82.
 metric, English equiv., table, 81.
 metric equivalents, table, 88.
 of cone, 134.
 of cylinder, 134.
 of prism, 133.
 of pyramid, 133.
 of solids, by calculus, 277.
 of sphere, measure of, in radii, 135.
 units of, equivalents, 66, 67.
 weight per, metric and English equivalents, table, 89.
Vulcanizer, rubber, 330.

W

Wall, walls,
 building-, weights of, 821.
 masonry, parts defined, 431,
 of buildings,
 reinforcement, 831.
 stonecutter's plan, 457.
 retaining-, 835.
Walnuts (trees), classification of, 343.
Wane, in lumber, defined, 387.
Waring's check valve, 1296.
Warren truss, chord stresses in, concentrated loads, 696.
Wash
 drill borings, cost data, 916.
 mill, in cement making, 405.
Washers,
 cast iron, weights and dimensions, table, 624.
 flat plate, weights and dimensions, table, 624.
 use of, 624.
Waste pipes, 1295.
 lead, table, 679.
Wasteway, length of, formula, (ref.) 859.
Water
 as road dust preventive, 1131.
 at maximum density, weight of, 85.
 boiling point of, 514.
 capacity and weight equivalents, table, 1376.
 consumption of, 1202.
 in cities, table, 1203.
 cranes, table, 1290.

Water—Cont'd.

- current meters, 1185.
- decomposition of, 316.
- density of, 67.
- duty of, in irrigation, tables, 1315-1317.
- effect of, on earth fill, 910.
- filtration, 1204.
 - cost, 1291.
- gallons per capita required in various cities, table, 1208.
- gas and gas-producer process, (ref.) 1377.
- gas tar, 1132.
- heads
 - for given pressures, table, 1147.
 - reduced to equivalent pressures, tables, 1148, 1149.
- hydrants, table, 1290.
- jet
 - concrete piles, 875.
 - for driving piles, (ref.) 890.
 - in pile driving, 873.
- (Lb. of) evaporated from and at 212° F., equiv. of, table, 91.
- measurement of,
 - by tank, 1182.
 - by venturi meter, 1182.
 - by weirs, 1182.
- meter, Pitot tube, 1183, 1184.
- metric weight of, 67.
- motors, described, 1336.
- physical properties of, table, 514.
- power
 - and steam power compared, 1385.
 - development, miscellaneous data (ref.) 1345.
 - formulas, 1332.
 - installation, economic size of pipe line for, 1189.
- pressures,
 - for given heads, tables, 1148, 1149.
 - reduced to equivalent heads, table, 1147.
- purification, 1204, 1292.
- rain-, weight of, 482.
- register, 1187.
 - instructions for installing, (ref.) 1187.
- screening, for domestic use, 1204.
- sea-,
 - at great depths, density of, 1145.
 - proof cement, 418.
 - weight of, 481, 482.
- storage and irrigation works of Southern California, (ref.) 1318.
- supply, 1190.
 - miscellaneous data, (ref.) 1201.
- surface, evaporation from, 1199.
- tank, elevated, 1207.
- tower, 1207.
- tube boilers, described, 1362.
- under pressure, density of, 1145.
- valves, 1271-1279, 1285-1287.
- vapor pressure of saturation for, table, 1373.

Water—Cont'd.

- weight of, 1145.
- table, 481.
- at various temperatures, table, 465.
- in pipes, table, 246-247.
- wheels,
 - described, 1336.
- Pelton,
 - quintex nozzle, table, 1342.
 - single nozzle, table, 1338-1341.
- works, 1202.
 - miscellaneous data, (ref.) 1291-1294.
- Waterways, 1320.
- Waterproof compositions, 418.
- Waterproofing
 - a reservoir, 1293.
- asphalt for, 418.
- concrete, 455.
- data for concrete, 453.
- oil-mixed concrete for, 455.
- Watt, watts,
 - equivalent of, table, 91.
- meter, defined, 1536.
- per second, equivalents, 90.
- per sq. inch, equiv. of, table, 91.
- units, single and compound, 1379.
- Wave, waves,
 - shape, in *elec.*, 1455.
 - ether, lengths of, 1380.
- Wax,
 - bees-, weight of, 482.
 - melting point of, 516.
- Weatherproof wire, table, 1435.
- Web
 - plates
 - of plate girders, properties of, table, 575.
 - (vert. line), properties of, 529.
 - stresses and shears, 307.
- Wedge, wedges,
 - circular cylindric-, properties of, 245.
 - common-, volume of, 249.
 - in *mech.*, formulas, 292.
 - of cone, 249.
- Week (time measure), 99.
- Weight, weights,
 - and dimensions of cast iron pipe and specials, tables, 1219-1267.
- and measures
 - (Foreign), American equivalents, table, 92-94.
 - of Philippines, English equivalents, 81.
 - and mass of water, metric, 67.
 - apothecaries', metric equivalents, table, 86.
 - avoirdupois,
 - long ton, metric equiv., table, 86.
 - short tons, metric equivalents, table, 86.
 - capacities and volumes, equivalents (1-9), table, 485.
 - defined, 469.
 - equivalent for any specific gravity, table, 483, 484.

- Weight, weights,—Cont'd.
 in *mech.*, defined, 278.
 measures and money, 66-99.
 metric and English
 equivalents, table, 89.
 equivalents (1-10), table, 85.
 metric, English equiv., table, 85.
 of brick, table, 474.
 of building stones, table, 474.
 of cast iron pipe, table, 1216.
 of cements, table, 474.
 of concrete, 475.
 cinder- and stone-, 455.
 of lime, 475.
 mortar, 475.
 of limestone, table, 475.
 of liquids, table, 468, 469.
 of marble, table, 476.
 of masonry, table, 476.
 of materials, 459.
 general table, 478.
 of sand, table, 476.
 of water at maximum density, 85.
 of woods, table, 470-473.
 per cubic foot, equiv. (1-9) in ca-
 pacities and volumes, table,
 485.
 per volume, metric and English
 equivalents, table, 89.
 reduced to specific gravities, table,
 474.
 trade-, of lumber, 391.
 troy, table, 86.
 Weir, weirs, 1177.
 center of pressure on, table, 1151.
 contracted, defined, 1177.
 formulas, 1178.
 Bazin's, 1178.
 Francis', 1178.
 Fteley and Stearns', 1180, 1181.
 Herschel's, 1181.
 Parmley's, 1180.
 instructions for installing, (ref.)
 1187.
 measurement of water, 1182.
 sharp-crested, surface, formulas,
 1178.
 standard, 1177.
 submerged, 1181.
 formulas, 1181.
 suppressed-, defined, 1177.
 triangular and trapezoidal, 1181.
 Weisenkalk (marl) for cement, 405.
 Weld, defined, 1836.
 Well, wells,
 artesian-, defined, 1190.
 boring, reference data, 1481.
 dia. to area, capacity, volume,
 weight (water), table, 246-7.
 driller for drilling blasting holes,
 cost, 926.
 Welded (lap-) pipe, 1269.
 Welding, borax for, 330.
 Welland canal, data, 1322.
 Wellhouse process, for ties, cost, 375.
 West point, of celestial sphere, de-
 fined, 201.
 Wet process, in cement making, 405.
 Wharton switch, 1088.
 Wharf, wharves,
 construction, 892.
 piers and docks, 892.
 reinforced concrete, (ref.) 900.
 Wheel gage, standard M. C. B., 1073.
 Wheels,
 Pelton,
 quintex nozzle, table, 1342.
 single nozzle, table, 1338-1341.
 water, described, 1336.
 Wheeled scrapers, grading with, cost
 data, 917.
 White
 lead for paint, 355.
 -metal, 398.
 zinc for paint, 355.
 Willow, willows,
 classification of, 344.
 weight of, 482.
 Wind
 loads on mill buildings, 833.
 pressure, 794.
 for bridges, 697.
 for buildings, 822.
 formulas, 794, 795.
 on cylinders, 797.
 on inclined surfaces, 795-797.
 on roofs, tables, 796, 797.
 on spheres, 797.
 railroad bridges, specifications,
 702.
 tables, 795, 796, 797.
 suction, 795.
 tension, 795.
 velocities attained, 794, 795.
 Window glass, cost prices, 479.
 Wire, wires,
 aluminum and copper compared,
 as electrical conductors, 496.
 bell-, elec. code rules, 1448.
 brass,
 physical properties of, table, 496.
 weight of, 478.
 brush, for mill scale, 359.
 capacity of, elec. code rules, table,
 1448.
 conduit-, elec. code rules, 1427.
 copper,
 and silicon-bronze compared, as
 electric conductors, 497.
 carrying capacity of, table, 1404.
 physical properties of, table,
 497.
 table, 1388-1391.
 weight of, 478.
 delta-metal, tensile strength of,
 table, 497.
 elec. code rules, 1399, 1403, 1405,
 1408, 1422, 1447.
 fixture-, elec. code rules, 1427.
 gages, tables, 666, 671.
 gold, tensile strength of, 497.
 in transmission lines,
 kinds and properties of, 1476.
 kind and size, 1386.
 insulated, table, 1423.
 iron, physical properties of, table,
 498.
 lead, tensile strength of, 498.

Wire, wires.—Cont'd.

- phosphor-bronze, tensile strength of, 497.
 - platinum, tensile strength of, 498.
 - Roebbling steel, properties of, 672.
 - rope, 673.
 - fastenings, 675.
 - tables, 674.
 - rubber-covered, tables, 1424.
 - silicon-bronze, tensile strength of, 497.
 - slow-burning, table, 1425.
 - steel,
 - physical properties of, table, 499.
 - weight of, 481.
 - weatherproof, table, 1425.
 - weight of, from specific gravity, table, 484.
 - car-, and equipment, elec. code rules, 1417.
 - theater-, elec. code rules, 1414.
- Wood (see, also, Timber),**
- alcohol, a tree product, 346.
 - as fuel, value of, 1363.
 - block pavement,
 - construction of, 1099.
 - creosoted, specifications, 1126.
 - specifications, 1103, 1120, 1128.
 - compression tests of, table, 490.
 - expansion coefficient of, 516.
 - friction of, 517-521.
 - (in machines), friction of, 521.
 - oil, weight of, 482.
 - paving blocks,
 - grooved, 1120.
 - treatment, analysis of, 1120.
- pipe,**
- bored and banded, 1208.
 - flow of water in, (ref.) 1187.
- screws, table, 622.**
- specific gravities of, table, 470-473.**
- stave connection with cast iron pipe, 1280.**
- stave pipe,**
- and details, table, 1210.
 - details of, 1208.
 - discharge through, table, 1210-1214.
 - durability of, 1187.
 - notes on, 1214.
- vinegar, 346.**
- weights of, table, 470-473.**
- Wood's fusible metal, melting point of, 515.**
- Wolfram, weight of, 482.**

Wooden

- beams,
 - for buildings, 819.
 - loads on, table, 566.
 - problems in, 567.
 - working stresses, table, 495.
- columns, working stresses, table, 495.
- moldings, elec. code rules, 1450.
- pipe, bored-, for water supply, 1207.
- stringers, bending moments, table, 791.

Wooden—Cont'd.

- structures, methods of preserving, 361.
 - ties,
 - cubic feet in, table, 1069.
 - feet B. M. in, table, 1070.
- Work**
- and power equivalents, metric and English, table, 90.
 - formula for, in hoisting, 290.
 - in *mech.*, equations of, 290.
- Working stress, -stresses,**
- defined, 487.
 - for reinforced concrete beams, 585.
 - for wooden beams and columns, table, 495.
- Worthington steam pump, 1367.**
- Wrought iron,**
- expansion coefficient of, 516.
 - for buildings, 819.
 - in buildings, safe stresses, 826.
 - manufacture of, 393.
 - melting point of, 515.
 - physical properties of, table, 498.
 - pipe, 1268.
 - standard, welded, tables, 677, 678.
 - weight of, 480.

X

- X-ray, 316.
- Xenon, *chem.*, 320.

Y

- Y's, cast iron pipe, tables, 1227, 1228, 1255, 1256.**
- Yard, yards,**
- and meters,
 - cubic,
 - equivalents, 88.
 - equiv. (1-10), table, 82.
 - equivalents, 88.
 - equiv. (1-10), table, 70.
 - square,
 - equivalents, 88.
 - equiv. (1-10), table, 80.
 - cubic,
 - equivalents, 66-67.
 - metric equivalent, 68.
 - metric equivalent, 68, 82.
 - (dollars per)
 - and francs per meter, equivalents (1-10), table, 98.
 - and marks per meter, 98.
 - equivalents, 68.
 - gravity-, (ref.) 1091.
 - inch and bushels, equiv. (1-9), table, 485.
 - inch and cubic feet, equiv. (1-9), table, 485.
 - inch and gallons, equiv. (1-9), table, 485.
 - metric equivalents, 66, 68.
 - square, metric equivalents, 68, 81
- Yarn**
- fiber, flax, strength of, 512.
 - in *cordage*, 668.

Year,
 common and leap-, time measure, 99.
 tropical, defined, 202.
 Yellow pine lumber,
 classification of, 387, 388.
 inspection of, 387, 388.
 Yen (Japanese), equiv. (1-10,-50-100) in U. S. money, table, 97.
 Yield point, defined, 487.
 Ytterbium, *chem.*, 320.
 Yttrium, *chem.*, 320.

Z

Z-bar, -bars,
 block, properties of, 533, 534.
 columns, dimensions and safe loads, tables, 598-600.
 rivet gages for, 614.
 rolled, properties of, 538.
 steel, properties of, table, 557.
 Z, block, properties of, 533, 534.
 Zenith
 distance, of a star, defined, 201.
 in *astron.*, defined, 947.
 of celestial sphere, defined, 201.

Zinc, *chem.*, 320.
 boiling point of, 514.
 cast-, physical properties of, 499.
 cast, etc, weight of, 482.
 chloride,
 cost, 375.
 for timber, 361.
 expansion coefficients of, 516.
 melting point of, 515.
 minerals, ores, 329.
 ores, uses of, 329.
 oxide for paint, 355.
 rolled-, tensile strength of, 499.
 uses of, 329.
 -white for calcimining, 355.
 white paint, 329.
 Zirconium, *chem.*, 320.
 Zone,
 of circle, mensuration of, 219.
 of circular spindle, 254.
 of parabolic sprindle, 254.
 of sphere,
 area of, by calculus, 276.
 defined, 135.
 mensuration of, 253.
 Zoological materials, 847.
